SURFACE WATER SUPPLY OF OHIO RIVER BASIN. 1917.

AUTHORIZATION AND SCOPE OF WORK.

This volume is one of a series of 14 reports presenting results of measurements of flow made on streams in the United States during the year ending September 30, 1917.

The data presented in these reports were collected by the United States Geological Survey under the following authority contained in the organic law (20 Stat. L., p. 394):

Provided, That this officer [the Director] shall have the direction of the Geological Survey and the classification of public lands and examination of the geological structure, mineral resources, and products of the national domain.

The work was begun in 1888 in connection with special studies relating to irrigation in the arid West. Since the fiscal year ending June 30, 1895, successive sundry civil bills passed by Congress have carried the following item and appropriations:

For gaging the streams and determining the water supply of the United States, and for the investigation of underground currents and artesian wells, and for the preparation of reports upon the best methods of utilizing the water resources.

Annual appropriations for the fiscal years ended June 30, 1895–1918.

1895	$12,500
1896	20,000
1897 to 1900, inclusive	50,000
1901 to 1902, inclusive	100,000
1903 to 1906, inclusive	200,000
1907	150,000
1908 to 1910, inclusive	100,000
1911 to 1917, inclusive	150,000
1918	175,000

In the execution of the work many private and State organizations have cooperated either by furnishing data or by assisting in collecting data. Acknowledgments for cooperation of the first kind are made in connection with the description of each station affected; cooperation of the second kind is acknowledged on page 11.

Measurements of stream flow have been made at about 4,240 points in the United States and also at many points in Alaska and the Hawaiian Islands. In July, 1917, 1,180 gaging stations were being maintained by the Survey and the cooperating organizations.

Many miscellaneous discharge measurements are made at other points. In connection with this work data were also collected in regard to precipitation, evaporation, storage reservoirs, river profiles, and water power in many sections of the country and will be made available in water-supply papers from time to time. Information in regard to publications relating to water resources is presented in the appendix to this report.

DEFINITION OF TERMS.

The volume of water flowing in a stream—the "run-off" or "discharge"—is expressed in various terms, each of which has become associated with a certain class of work. These terms may be divided into two groups—(1) those that represent a rate of flow, as second-feet, gallons per minute, miners' inches, and discharge in second-feet per square mile, and (2) those that represent the actual quantity of water, as run-off in depth of inches, acre-feet, and millions of cubic feet. The principal terms used in this series of reports are second-feet, second-feet per square mile, run-off in inches, and acre-feet. They may be defined as follows:

"Second-feet" is an abbreviation for "cubic feet per second." A second-foot is the rate of discharge of water flowing in a channel of rectangular cross section 1 foot wide and 1 foot deep at an average velocity of 1 foot per second. It is generally used as a fundamental unit from which others are computed.

"Second-feet per square mile" is the average number of cubic feet of water flowing per second from each square mile of area drained, on the assumption that the run-off is distributed uniformly both as regards time and area.

"Run-off (depth in inches)" is the depth to which an area would be covered if all the water flowing from it in a given period were uniformly distributed on the surface. It is used for comparing run-off with rainfall, which is usually expressed in depth of inches.

An "acre-foot," equivalent to 43,560 cubic feet, is the quantity required to cover an acre to the depth of 1 foot. The term is commonly used in connection with storage for irrigation.

The following terms not in common use are here defined:

"Stage-discharge relation," an abbreviation for the term "relation of gage height to discharge."

"Control," a term used to designate the section or sections of the stream below the gage which determines the stage-discharge relation at the gage. It should be noted that the control may not be the same section or sections at all stages.

The "point of zero flow" for a gaging station is that point on the gage—the gage height—to which the surface of the river would fall if there were no flow.

WATER-STAGE RECORDERS.

EXPLANATION OF DATA.

The data presented in this report cover the year beginning October 1, 1916, and ending September 30, 1917. At the beginning of January in most parts of the United States much of the precipitation in the preceding three months is stored as ground water in the form of snow or ice, or in ponds, lakes, and swamps, and this stored water passes off in the streams during the spring break-up. At the end of September, on the other hand, the only stored water available for run-off is possibly a small quantity in the ground; therefore the run-off for the year beginning October 1 is practically all derived from precipitation within that year.

The base data collected at gaging stations consist of records of stage, measurements of discharge, and general information used to supplement the gage heights and discharge measurements in determining the daily flow. The records of stage are obtained either from direct readings on a staff gage or from a water-stage recorder that gives a continuous record of the fluctuations. Measurements of discharge are made with a current meter. (See Pls. I, II.) The general methods are outlined in standard textbooks on the measurement of river discharge.

From the discharge measurements rating tables are prepared that give the discharge for any stage, and these rating tables, when applied to gage heights, give the discharge from which the daily, monthly, and yearly mean discharge is determined.

The data presented for each gaging station in the area covered by this report comprise a description of the station, a table giving results of discharge measurements, a table showing the daily discharge of the stream, and a table of monthly and yearly discharge and run-off.

If the base data are insufficient to determine the daily discharge, tables giving daily gage heights and results of discharge measurements are published.

The description of the station gives, in addition to statements regarding location and equipment, information in regard to any conditions that may affect the constancy of the stage-discharge relation, covering such subjects as the occurrence of ice, the use of the stream for log driving, shifting of control, and the cause and effect of backwater; it gives also information as to diversions that decrease the flow at the gage, artificial regulation, maximum and minimum recorded stages, and the accuracy of the records.

The table of daily discharge gives, in general, the discharge in second-feet corresponding to the mean of the gage heights read each day. At stations on streams subject to sudden or rapid diurnal fluctuation the discharge obtained from the rating table and the mean daily gage height may not be the true mean discharge for the day. If such stations are equipped with water-stage recorders the mean daily discharge may be obtained by averaging discharge at regular intervals during the day, or by using the discharge integrator, an instrument operating on the principle of the planimeter and containing as an essential element the rating curve of the station.

In the table of monthly discharge the column headed "Maximum" gives the mean flow for the day when the mean gage height was highest. As the gage height is the mean for the day it does not indicate correctly the stage when the water surface was at crest height, and the corresponding discharge was consequently larger than given in the maximum column. Likewise, in the column headed "Minimum" the quantity given is the mean flow for the day when the mean gage height was lowest. The column headed "Mean" is the average flow in cubic feet for each second during the month. On this average flow computations recorded in the remaining columns, which are defined on page 8, are based.

ACCURACY OF FIELD DATA AND COMPUTED RESULTS.

The accuracy of stream-flow data depends primarily (1) on the permanence of the discharge relation and (2) on the accuracy of observation of stage, measurements of flow, and interpretation of records.

A paragraph in the description of the station or footnotes added to the tables gives information regarding the (1) permanence of the stage-discharge relation, (2) precision with which the discharge rating curve is defined, (3) refinement of gage readings, (4) frequency of gage readings, and (5) methods of applying daily gage heights to the rating table to obtain the daily discharge.[1]

For the rating tables "well defined" indicates, in general, that the rating is probably accurate within 5 per cent; "fairly well defined," within 10 per cent; "poorly defined," within 15 to 25 per cent. These notes are very general and are based on the plotting of the individual measurements with reference to the mean rating curve.

The monthly means for any station may represent with high accuracy the quantity of water flowing past the gage, but the figures showing discharge per square mile and depth of run-off in inches may be subject to gross errors caused by the inclusion of large noncontributing districts in the measured drainage area, by lack of information concerning water diverted for irrigation or other use, or by inability to interpret the effect of artificial regulation of the flow of the river above the station. "Second-feet per square mile" and "Run-off (depth in inches)" are therefore not computed if such errors appear probable. The computations are also omitted for stations on streams draining areas in which the annual rainfall is less than 20 inches. All figures representing "second-feet per square mile" and

[1] For a more detailed discussion of the accuracy of stream-flow data see Grover, N. C., and Hoyt, J. C. Accuracy of stream-flow data: U. S. Geol. Survey Water-Supply Paper 400, pp. 53-59, 1916.

"run-off (depth in inches)" previously published by the Survey should be used with caution because of possible inherent sources of error not known to the Survey.

The table of monthly discharge gives only a general idea of the flow at the station and should not be used for other than preliminary estimates; the tables of daily discharge allow more detailed studies of the variation in flow. It should be borne in mind, however, that the observations in each succeeding year may be expected to throw new light on data previously published.

COOPERATION.

Work in Illinois during the year ending September 30, 1917, was carried on in cooperation with the State of Illinois Rivers and Lakes Commission.

Work in Kentucky was done in cooperation with the State Geological Survey, J. B. Hoeing, State geologist.

The United States Engineer Corps cooperated in the maintenance of 9 gaging stations in the Ohio River basin and furnished base data for 30 additional stations.

Financial assistance was also rendered by the Alabama Geological Survey and The Tennessee Power Co.

DIVISION OF WORK.

Data for Allegheny River at Red House, N. Y., were collected and prepared for publication under the direction of C. C. Covert, district engineer, assisted by O. W. Hartwell and E. D. Burchard.

Data for the Ohio River basin, except those for the Allegheny at Red House, N. Y., for stations in Illinois, and for the basin of Tennessee River, were collected and prepared for publication under the direction of A. H. Horton, district engineer, assisted by B. E. Jones, B. J. Peterson, and B. L. Hopkins.

Data for stations in Illinois in Ohio basin were collected and prepared for publication under direction of W. G. Hoyt, district engineer, assisted by H. C. Beckman.

Field data for stations in the Tennessee River basin were collected under the direction of Warren E. Hall, district engineer, assisted by L. J. Hall. The records were prepared for publication under the direction of C. G. Paulsen, district engineer, assisted by B. J. Peterson and B. L. Hopkins.

The records were assembled and reviewed by A. H. Horton, B. E. Jones, and B. J. Peterson, and B. L. Hopkins.

GAGING-STATION RECORDS.

ALLEGHENY RIVER BASIN.

ALLEGHENY RIVER AT RED HOUSE, N. Y.

Location.—At highway bridge in Red House, Cattaraugus County, 5 miles below Salamanca and 13 miles above boundary between New York and Pennsylvania. Conewango Creek, the outlet of Chautauqua Lake, enters the Allegheny in Pennsylvania about 30 miles below the station.

Drainage area.—1,640 square miles.

Records available.—September 4, 1903, to September 30, 1917.

Gage.—Gurley seven-day water-stage recorder on left bank just below highway bridge; installed September 3, 1917; prior to this date, chain gage attached to upstream side of bridge near left end. Gage read and recorder inspected by W. E. Coe.

Discharge measurements.—Made from downstream side of bridge.

Channel and control.—Coarse gravel; shifting occasionally.

Extremes of discharge.—Maximum stage recorded during year, 9.35 feet at 3 p. m. March 12 (discharge, 17,600 second-feet); minimum stage recorded, 3.15 feet October 6, 11, and 12 (discharge, 238 second-feet).

1903–1917: Maximum stage recorded, 12.7 feet March 26, 1913 (discharge, about 40,000 second-feet); minimum stage recorded, 2.7 feet on several days in December, 1908 (discharge about 100 second-feet).

Ice.—Stage-discharge relation somewhat affected by ice.

Regulation.—Low-water flow may be slightly affected by the operation of several small power plants above Salamanca. A storage reservoir on the divide between Oil Creek, tributary to Allegheny River, and Genesee River, tributary to Lake Ontario, was formerly used for supplying water to the Erie Canal system through the abandoned Genesee River Canal and Genesee River. The reservoir is no longer used for canal purposes, and the water is all turned into Allegheny River through Olean Creek.

Accuracy.—Stage-discharge relation practically permanent between dates of shifting; affected by ice during most of February. Rating curve well defined between 300 and 900 second-feet and between 6,000 and 13,000 second-feet. Gage read to half tenths twice daily. Operation of water-stage recorder satisfactory September 3–14 and 29–30; daily gage height for this period determined by inspecting recorder graph. Daily discharge ascertained by applying mean daily gage height to rating table. Open-water records good; others fair.

Discharge measurements of Allegheny River at Red House, N. Y., during the year ending Sept. 30, 1917.

MONONGAHELA RIVER BASIN.

TYGART RIVER NEAR DAILEY, W. VA.

LOCATION.—At Burnt Bridge, on Staunton-Parkersburg pike 1 mile northeast of Dailey, Randolph County, 2 miles south of Beverly, on Western Maryland Railroad. Stalnaker Run enters river on right about 1,000 feet below station and above control.

DRAINAGE AREA.—194 square miles (measured on topographic maps).

RECORDS AVAILABLE.—April 20, 1915, to September 30, 1917.

GAGE.—Vertical staff on face of right abutment of bridge near downstream end; read by Charles W. Chenoweth.

DISCHARGE MEASUREMENTS.—Made from bridge or by wading. Stay wire is used for measurements at high stages. Flow of Stalnaker Run is included.

CHANNEL AND CONTROL.—One channel at all stages, straight for 100 feet above and 1,300 feet below bridge. Right bank high; left bank low; large overflow through meadows at high stages. Stream bed is rocky, but banks are sandy. Control probably permanent. Point of zero flow, September 26, 1917, at gage height, 0.2 foot $\pm$ 0.1 foot.

EXTREMES OF STAGE.—Maximum stage recorded during year, 13.4 feet at 7 a. m., March 12; minimum stage, 0.6 foot at 7 a. m., September 6, 1916. Highest known flood reached a stage represented by gage height about 16 feet.

ICE.—Stage-discharge relation affected by ice at times.

ACCURACY.—Stage-discharge relation probably permanent; affected by ice during December, January, and February. Rating curve not yet developed. Gage read twice daily to half-tenths. Records good.

COOPERATION.—Station maintained in cooperation with United States Engineer Corps.

Discharge measurements of Tygart River near Dailey, W. Va., during the year ending Sept. 30, 1917.

NOTE.—No gage readings Feb. 7-9, 12-16, and 19. Gage read to top of ice Dec. 14-21, Jan. 15, Feb. 3, 5, 10, 11, 17, 18.

TYGART RIVER AT BELINGTON, W. VA.

LOCATION.—At highway bridge at Belington, Barbour County, one-fourth mile above mouth of Mill Creek.

DRAINAGE AREA.—390 square miles.

RECORDS AVAILABLE.—June 5, 1907, to September 30, 1917.

GAGE.—Chain gage attached to the upstream side of highway bridge to left of center of the river; read by S. A. Campbell. Sea-level elevation of zero of gage, 1,679.89 feet.

DISCHARGE MEASUREMENTS.—Made from upstream side of the bridge.

CHANNEL AND CONTROL.—Practically permanent; straight above and below.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 21.48 feet at 7.30 a. m., March 13 (discharge about 20,000 second-feet); minimum stage, 2.01 feet at 7 a. m., August 29 and September 30 (discharge 14 second-feet).

ICE.—Ice may affect stage-discharge relation for short periods during December, January, and February.

ACCURACY.—Stage-discharge relation practically permanent; apparently little affected by ice during 1917. Daily discharge determined from rating curve well defined between 300 and 4,000 second-feet, fairly well defined between 13 and 300 second-feet; beyond these limits curve is extension. Gage read daily in the morning to hundredths. Daily discharge ascertained by applying mean daily gage heights to rating table. Open-water rating curve used to determine winter discharge, as effect of ice on stage-discharge relation was considered small.

The following discharge measurement was made by Peterson and Hopkins: September 22, 1917—Gage height, 2.16 feet; discharge, 23.8 second-feet.

Daily discharge, in second-feet, of Tygart River at Belington, W. Va., for the year ending Sept. 30, 1917.

TYGART RIVER AT FETTERMAN, W. VA.

Location.—At highway bridge at Fetterman, Taylor County, three-fourths mile above mouth of Otter Creek.

Drainage area.—1,340 square miles.

Records available.—June 3, 1907, to September 30, 1917.

Gage.—Chain gage attached to downstream side of highway bridge; read by Joseph Weaver. Sea-level elevation of zero of gage, 957.86 feet.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge.

CHANNEL AND CONTROL.—Practically permanent.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 21.1 feet at 7 a. m. January 22 (discharge about 36,000 second-feet); minimum stage, 3.13 feet August 24 and morning of August 25 (discharge, 54 second-feet).

No records of floods previous to installation of gage; highest stage recorded since station was established, 29.1 feet, in July, 1912.

ICE.—Ice probably affects stage-discharge relation for short periods in severe winters.

ACCURACY.—Stage-discharge relation practically permanent. Affected by ice December 17-20 and February 4–19. Rating curve well defined between 100 and 23,000 second-feet, poorly defined below 100 second-feet; above 23,000 second-feet the curve is an extension. Gage read twice daily to half-tenths. Discharge ascertained by applying mean daily gage heights to rating table. Estimates of daily discharge during periods stage-discharge relation was affected by ice are poor; the records for other periods are good.

The following discharge measurement was made by Peterson and Hopkins: September 21, 1917: Gage height, 3.26 feet; discharge, 79.4 second-feet.

Daily discharge, in second-feet, of Tygart River at Fetterman, W. Va., for the year ending Sept. 30, 1917.

MONONGAHELA RIVER AT LOCK 15, HOULT, W. VA.

Location.—At Lock 15, at Hoult, 2½ miles below county highway bridge at Fairmont, Marion County, and 4 miles below mouth of West Fork. Buffalo Creek enters on left three-fourths mile above station.

Drainage area.—2,430 square miles (measured on topographic maps).

Records available.—April 7, 1915, to September 30, 1917. Upper and lower gages at Lock 15 have been read under direction of United States Engineer Corps since May 1, 1904.

Gage.—Upper gage at lock; lower section is set in recess in left lock wall just above upper gate; upper section is 61.5 feet from face of right lock wall, directly opposite lower section. Read by Charles R. Hall, lockmaster.

Discharge measurements.—Made from bridge at Fairmont or by wading on crest of dam. Flow of Buffalo Creek is added to discharge measured at bridge.

Channel and control.—One channel at all stages; straight half a mile above and below bridge. Control of station is crest of dam; permanent. Point of zero flow, gage height 6.9 feet, elevation of crest of dam. Leakage through lock and occasional opening of valves of lock may affect stage at which flow would be zero.

Extremes of discharge.—Maximum stage recorded during 1917, 21.0 feet at 11 a. m. January 22 (discharge, 90,300 second-feet); minimum stage, 6.60 feet at 7 p. m. August 24, 1916, due to opening the valves. Flood of 1888, before dam No. 15 was built, reached a stage represented by gage height about 26 feet.

Ice.—Stage-discharge relation affected by ice when ice in pool above dam forms close to crest of dam.

Diversions.—Leakage through lock and water used for lockages. See "Accuracy."

Regulation.—None under normal conditions. Pool No. 15 may be lowered at times in the interest of navigation.

ACCURACY.—Stage-discharge relation permanent except for effect of operations at lock and change in leakage through lock, the change depending on which gates are open; affected by ice December 17–20 and February 7–18. Rating curve well defined to 62,000 second-feet. Gage read twice daily to hundredths, beginning April 7, 1915; prior to that date, at 8 a. m. daily to tenths. Daily discharge ascertained by applying mean daily gage heights to rating table, and adding amount of water used for lockage. Rating table makes allowance based on measurement for leakage through upper gates, for under normal conditions upper gates are closed; gage reader records number of lockages and length of time upper gates are open. Daily discharge April 7, 1915, to September 30, 1917, corrected for effect of lockage and change in leakage when upper gates at lock are open. Data for correcting earlier records nor available.

Discharge August 23, 24, and 25 interpolated because valves at lock were open for considerable periods with little or no flow over the dam. Results considered good except for periods when daily discharge was estimated because of ice or interpolated because of opening valves at lock and lowering pool.

COOPERATION.—Station maintained in cooperation with United States Engineer Corps.

The following measurement of leakage through the lower gates, Lock 15, was made by Peterson and Hopkins:

October 3, 1917: Gage height, 7.10 feet; discharge, 120 second-feet. The lower gates were shut and upper gates open.

Discharge measurements of Monongahela River at Lock 15, Hoult, W. Va., during the year ending Sept. 30, 1917.

[Made by B. E. Jones.]

MIDDLE FORK AT MIDVALE, W. VA.

Location.—About one-third mile above Midvale railroad station on Coal & Coke Railroad, two-thirds mile below post office at Ellamore, Randolph County. Laurel Creek enters river on right about 1¾ miles above station.

Drainage area.—122 square miles (measured on topographic maps).

Records available.—May 3, 1915, to September 30, 1917.

Gage.—Vertical and inclined staff on right bank; read by Anna Riley.

Discharge measurements.—Made from cable or by wading short distance below gage.

Channel and control.—One channel at all stages; straight 300 feet above and 100 feet below cable section. Both banks are high and in most places wooded. Control probably permanent.

Extremes of discharge.—Maximum stage recorded during year, 10.67 feet at 7 a. m. March 12, 1917 (discharge, about 4,590 second-feet); minimum stage, 1.12 feet at 7 a. m. August 29, 1917 (discharge, 2.6 second-feet). Floods of 1888 and 1912 reached gage height of about 18 feet.

Ice.—Stage-discharge relation affected by ice for short periods in severe winters.

Accuracy.—Stage-discharge relation practically permanent; affected by ice to slight extent December 19–21, January 12–15, and considerably February 2–17. Rating curve well defined below 1,600 second-feet; above this point, curve is an extension. Gage read twice daily to hundredths. Discharge ascertained by applying mean daily gage heights to rating table. Daily discharge for periods in December and January affected by ice are probably in error to a small extent. Estimated mean flow February 2–17 may be considerably in error; records for rest year are excellent.

Cooperation.—Station maintained in cooperation with United States Engineer Corps.

The following discharge measurements were made during the year by B. E. Jones and by Peterson and Hopkins, respectively:

April 7, 1917: Gage height, 2.97 feet; discharge, 261 second-feet.

September 27, 1917: Gage height, 1.22 feet; discharge, 5.1 second-feet.

Daily discharge, in second-feet, of Middle Fork at Midvale, W. Va., for the year ending Sept. 30, 1917.

BUCKHANNON RIVER AT HALL, W. VA.

Location.—About 500 feet below ruins of an old milldam, one-fourth mile above post office and county highway bridge at Hall, Barbour County, 1 mile from Baltimore & Ohio Railroad station. Pecks Run enters river on left 1 mile below station.

Drainage area.—277 square miles (measured on topographic maps).

Records available.—April 15, 1915, to September 30, 1917. June 7, 1907, to May 25, 1909, chain gage at county highway bridge.

Gage.—Vertical and inclined staff on right bank; read by James Newcomb.

Discharge measurements.—Made from county highway bridge. Stay wire used for measurements at high stages.

Channel and control.—Gage is about midway between beginning and end of rapids, having approximately 10 feet fall. Bed of stream in rapids composed of boulders, rocks, and gravel; should be fairly permanent. Both banks are high and wooded and are not overflowed except into an old mill race on left bank.

Extremes of discharge.—Maximum stage recorded during year, 11.70 feet at 5 p. m. March 12, 1917 (discharge, 9,630 second-feet); minimum stage, 1.70 feet at 6 a. m. September 27, 1917 (discharge, 8.5 second-feet).

Highest flood known reported to have reached a gage height of about 14 feet in 1888.

Ice.—Stage-discharge relation affected by ice during severe winters.

Diversions.—No water diverted above station except small quantity which may flow around gage in abandoned mill race above ordinary low stages and which is included in flow measured at county highway bridge.

Accuracy.—Stage-discharge relation practically permanent; affected by ice February 4–15. Rating curve well defined between 40 and 4,500 second-feet; extended beyond these limits. Gage read twice daily to hundredths. Daily discharge ascertained by applying mean daily gage heights to rating table. Record excellent except for period February 4–15, for which daily discharge was estimated because of ice.

Cooperation.—Station maintained in cooperation with United States Engineer Corps.

The following discharge measurement was made by Peterson and Hopkins:
September 28, 1917: Gage height, 1.77 feet; discharge, 11.7 second-feet.

Daily discharge, in second-feet, of Buckhannon River at Hall, W. Va., for the year ending Sept. 30, 1917.

WEST FORK AT BUTCHERVILLE, W. VA.

Location.—At Weston & Clarksburg Electric Railway Co.'s trolley bridge, one-fourth mile upstream from Butcherville, Lewis County, about 3 miles north of Weston. Freemans Creek enters river on left about a mile below station.

Drainage area.—181 square miles (measured on topographic maps).

Records available.—April 8, 1915, to September 30, 1917.

Gage.—Chain gage fastened to upstream side of trolley bridge near center of span; read by Bess Ervin.

Discharge measurements.—Made from bridge or by wading.

Channel and control.—One channel except at extreme high stages, when river overflows right bank and a little water passes through two small culverts in trolley embankment; straight for 500 feet above and curved for 1,000 feet below station. Stream bed is sand and gravel, but is solid rock at riffle below gage. Control probably permanent. Growth of aquatic plants may cause backwater at gage during summer months.

Extremes of stage.—Maximum stage recorded during year, 20.01 feet at 8.30 a. m. March 12, 1917; minimum stage, 3.52 feet at 9.30 a. m. August 22, 1917.

Highest flood known is reported to have reached a stage represented by gage height of about 27 feet in 1888. Dam since washed out may have increased height of this flood.

Ice.—Stage-discharge relation affected by ice in severe winters.

Accuracy.—Stage-discharge relation probably permanent, probably affected by ice in December and February. Measurements of flow do not indicate serious backwater from growth of aquatic plants. Gage read twice daily to hundredths. Records excellent. Data inadequate for determining daily discharge.

Cooperation.—Station maintained in cooperation with United States Engineer Corps.

Discharge measurements of West Fork at Butcherville, W. Va., during the year ending Sept. 30, 1917.

Date.	Made by—	Gage height.	Discharge.

Note.—Gage heights Dec. 16, Feb. 5, 6, 7 to top of ice.

WEST FORK AT ENTERPRISE, W. VA.

Location.—At highway bridge at Enterprise, Harrison County, three-fourths mile above mouth of Bingamon Creek.

Drainage area.—750 square miles.

Records available.—June 2, 1907, to September 30, 1917.

Gage.—Chain gage attached to bridge; read by C. M. Tetrick. Sea-level elevation of zero of gage, 869.91 feet.

Discharge measurements.—Made from downstream side of bridge.

Channel and control.—Channel at measuring section broken by one pier; smooth rock bottom. Straight above and below. Control practically permanent.

Extremes of stage.—Maximum stage recorded during year, 25.35 feet at 8 a. m. January 22, 1917; minimum stage, 0.7 foot July 2, 1917.

1907–1917: Maximum stage recorded, January 22, 1917. Flood of 1888 reached stage represented by about 33 feet referred to datum of present gage.

Ice.—Stage-discharge relation may be affected by ice for short periods during December, January, and February.

Accuracy.—Stage-discharge relation practically permanent; affected by ice the first half of February and parts of December and January. A measurement made October 2, 1917, indicates a marked change in the rating curve or that the operation of the mill at the dam at Worthington about 3 miles below the gage affects the gage readings. The gates of the mill dam were open December 5–12, 1908, in order to drain the pond, but no effect was apparent on the gage readings, which may have been due to unreliable gage readings. The low-water discharge, as published in previous Water-Supply Papers, for this station may at times be in error; this condition should be observed in using the data. Gage read once daily to half-tenths. Comparison with the flow at other gaging stations in the Monongahela basin apparently indicates gage readings are unreliable at times.

The following discharge measurement was made by Peterson and Hopkins: October 2, 1917: Gage height, 1.08 feet; discharge, 10.3 second-feet.

Daily gage height, in feet, of West Fork at Enterprise, W. Va., for the year ending Sept. 30, 1917.

Note.—Gage readings probably affected by backwater from ice portions of December, January, and February 1-15.

ELK CREEK NEAR CLARKSBURG, W. VA.

Location.—At a footbridge near Clarksburg, Harrison County, 300 feet above Turkey Run and about 6 miles above mouth of creek.

Drainage area.—107 square miles (determined by Pittsburgh Flood Commission).

Records available.—October 11, 1910, to September 30, 1917.

Gage.—Wooden staff gage fastened to a tree near right abutment of footbridge; read by E. H. Smith. Sea-level elevation of zero of gage, 955.01 feet.

Discharge measurements.—Made from footbridge or by wading at section about 200 feet below bridge.

Channel and control.—Rocky and practically permanent; banks high and not subject to overflow. Point of zero flow, about gage height 0.9 foot.

Extremes of stage.—Maximum stage recorded during year, 11.26 feet at 10 a. m. January 22, 1917; minimum stage recorded, 1.11 feet at 10 a. m. September 24–25.

The flood of July, 1912, reached stage represented by 15 feet on the present gage.

Ice.—Stage-discharge relation may be affected by ice for short periods in December, January, and February.

Accuracy.—Stage-discharge relation practically permanent, probably affected by ice a portion of February, 1917. Gage read daily in the morning to half-tenths. Records good. Data inadequate for determination of daily discharge.

The following discharge measurements were made by B. J. Peterson and B. E. Jones, respectively:

January 23, 1917: Gage height, 3.30 feet; discharge, 500 second-feet.

March 14, 1917: Gage height, 4.21 feet; discharge, 1,010 second-feet.

Daily gage height, in feet, of Elk Creek near Clarksburg, W. Va., for the year ending Sept. 30, 1917.

BUFFALO CREEK AT BARRACKVILLE, W. VA.

Location.—At steel highway bridge about 1,000 feet above covered highway bridge at Barrackville, Marion County, 2¾ miles northwest of Fairmont. Finch's Run enters on left about 1,600 feet below station.

Drainage area.—115 square miles (measured on topographic maps).

Records available.—May 8, 1915, to September 30, 1917; June 3, 1907, to December 31, 1908.

Gage.—Chain gage fastened to downstream hand rail of bridge; read by E. M. Beall.

Discharge measurements.—Made from highway bridge or by wading. Stay wire is used for measurements at high stages.

Channel and control.—One channel at all stages; straight about 100 feet above and below station. Both banks high. Stream bed rocky, some gravel. Control changes during severe floods.

Extremes of discharge.—Maximum stage recorded during year, 14.22 feet at 7.45 a. m. January 22, 1917 (discharge about 6,800 second-feet); minimum discharge, 0.4 second-foot Sept. 22–30.

Flood of July, 1912, reached a stage represented by about 16 feet on present gage.

Ice.—Stage-discharge relation affected by ice during severe winters.

Accuracy.—Stage-discharge relation not permanent, changed during the flood of January 22, 1917. Rating curve used October 1, 1916, to January 21, 1917, and curve used January 22 to September 30, 1917, well defined below 1,600 second-feet; above 1,600 second-feet, the curve is an extension. Gage read twice daily to hundredths except Sunday, when gage is read once. Daily discharge ascertained by applying mean daily gage heights to rating table except as follows: October 27, December 3, 4, 5, July 16, discharge interpolated because of missing gage readings. December 15–20, and February 4–19, estimated because of ice. Records good except those interpolated or estimated, which are poor.

Cooperation.—Station maintained in cooperation with United States Engineer Corps.

The following discharge measurement was made by B. J. Peterson and B. L. Hopkins: October 3, 1917: Gage height, 0.67 foot; discharge, 0.55 second-foot.

Daily discharge, in second-feet, of Buffalo Creek at Barrackville, W. Va., for the year ending Sept. 30, 1917.

Day.	Oct.	Nov.	Dec.	Jan.	Feb.	Mar.	Apr.	May.	June.	July.	Aug.	Sept.

CHEAT RIVER NEAR PARSONS, W. VA.

Location.—At Moss highway bridge, 2 miles north of Parsons, Tucker County, 2 miles below junction of Shavers Fork, and 5 miles below junction of Dry Fork and Blackwater River.

Drainage area.—716 square miles (determined by Hydroelectric Co. of West Virginia).

Records available.—January 1, 1913, to September 30, 1917.

Gage.—Chain gage near center of bridge on downstream guard rail; read by Mrs. E. C. Linger.

Discharge measurements.—Made from downstream side of highway bridge.

Channel and control.—Rocky and probably permanent. Water is swift and turbulent.

Extremes of discharge.—Maximum stage recorded during year, 17.98 feet at 7 a. m. March 12 (discharge about 40,000 second-feet); minimum stage, 1.52 feet at 7 a. m. November 1 (discharge, 29 second-feet).

Ice.—Stage-discharge relation affected by ice during severe winters.

Regulation.—Some regulation above at various pulp mills and sawmills. Effect probably compensating, so that two gage readings per day give correct basis for determining discharge.

Accuracy.—Stage-discharge relation practically permanent; probably affected by ice for short periods in December, January and February. Rating curve fairly well defined between 65 and 5,500 second-feet. Beyond these limits the curve is an extension and may be in considerable error. Gage read twice daily to quarter tenths. Daily discharge ascertained by applying mean daily gage heights to rating table. Discharge December 10–22, 29–31, January 12–20, and February 2–17, may be somewhat large due to not correcting discharge for effect of ice on gage readings. Records fair except for those periods effected by ice, which are poor.

Cooperation.—Station maintained in cooperation with the Hydroelectric Co. of West Virginia.

The following discharge measurement was made by B. J. Peterson and B. L. Hopkins:

September 25: Gage height, 1.88 feet, discharge, 74 second-feet.

Daily discharge, in second-feet, of Cheat River near Parsons, W. Va., for the year ending Sept. 30, 1917.

Day.	Oct.	Nov.	Dec.	Jan.	Feb.	Mar.	Apr.	May.	June.	July.	Aug.	Sept.

CHEAT RIVER AT ROWLESBURG, W. VA.

Location.—At Baltimore & Ohio Railroad bridge at Rowlesburg, Preston County, about 300 feet above mouth of Salt Lick Creek.

Drainage area.—960 square miles (includes drainage area of Salt Lick Creek).

Records available.—July 19, 1912, to September 30, 1917. The United States Weather Bureau has collected gage-height records since 1884.

Gage.—Mott tape gage attached to upstream side of bridge; read by J. F. Pierce.

Discharge measurements.—Made from upstream side of bridge. Salt Lick Creek is measured separately and the discharge added to that measured at the bridge.

Channel and control.—Stream is curved above and below bridge; control consists of small boulders; probably permanent. Salt Lick Creek enters between the control and the gage. Stage at which flow would be zero was about 0.45 foot in September, 1917.

Extremes of stage.—Maximum stage recorded during year, 12.8 feet March 12; minimum stage, 2.0 feet August 20, 22, 23, 29, and September 23.

The highest stage of which there is any record occurred, according to the United States Weather Bureau, July 10, 1888, when the water reached a stage of 22 feet.

Ice.—Stage-discharge relation affected by ice during severe winters.

Accuracy.—Stage-discharge relation probably permanent; affected by ice December 16-21, January 15-21, and February 4-18. Data inadequate for determining daily discharge. Gage read daily in the morning to tenths.

Cooperation.—Gage-height record furnished by the United States Weather Bureau.

The following measurements were made by B. J. Peterson and B. L. Hopkins September 20, 1917: Gage height, 2.23 feet; discharge, 161 second-feet. Gage height, 2.22 feet; discharge, 155 second-feet.

Daily gage height, in feet, of Cheat River at Rowlesburg, W. Va., for the year ending Sept. 30, 1917.

CHEAT RIVER NEAR MORGANTOWN, W. VA.

Location.—At highway bridge at Uneva, Monongalia County, 10 miles above mouth of river. Parallel of 39° 40′ crosses the river at this bridge.

Drainage area.—1,380 square miles.

Records available.—July 8 to December 30, 1899; July 1 to December 29, 1900; August 21, 1902, to December 31, 1905; November 18, 1908, to September 30, 1917.

Gage.—Chain gage attached to bridge; read by C. F. Baker.

Discharge measurements.—Made from upstream side of bridge or by wading.

Channel and control.—Probably permanent.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 13.67 feet at 5 p. m. March 12 (discharge about 51,000 second-feet); minimum stage, 1.97 feet August 30 and several days the latter part of September (discharge, 162 second-feet).

ICE.—Ice forms sometimes to a thickness of several inches, and large ice jams may affect the stage-discharge relation during short periods in December, January, and February.

ACCURACY.—Stage-discharge relation practically permanent; affected by ice portions of December, January, and February. Rating curve used for 1917 fairly well defined above 175 second-feet. Discharge measurements made November 30, 1914, October 4 and 5, 1917, indicate a marked change in the stage-discharge relation below gage height 2.4 feet (discharge, 410 second-feet) and a new rating curve was drawn for 1917. Change from the former rating curve ranges from 0 at discharge 445 second-feet to 30 per cent at discharge 163 second-feet, the rating curve for 1917 giving smaller results. Date of change not known, but may have been some time during 1914. In view of the uncertainty in the date of this change in stage-discharge relation, estimates of daily discharge for the years 1914 to 1916 may be subject to considerable error below 410 second-feet. Gage read twice daily to hundredths. Daily discharge ascertained by applying mean daily gage heights to the rating table. Discharge interpolated because of missing gage readings, October 28, November 4, 6, 12, 23, December 12, 25, January 13, February 28, April 5, May 10, 26, July 29, September 9, 16; estimated because of ice from climatic data and observer's notes, December 15–21, January 15, 16, 19, 20, February 11, 18. Results good except for periods probably affected by ice, December 10–22, January 15, 16, and February 6–20, for which they are probably poor.

The following discharge measurements were made by Peterson and Hopkins:

October 4, 1917: Gage height, 2.06 feet; discharge, 192 second-feet.

October 5, 1917: Gage height, 2.06 feet; discharge, 196 second-feet.

Daily discharge, in second-feet, of Cheat River near Morgantown, W. Va., for the year ending Sept. 30, 1917.

BLACKWATER RIVER AT HENDRICKS, W. VA.

LOCATION.—At highway bridge at Hendricks, Tucker County, about one-eighth mile above mouth of river.

DRAINAGE AREA.—148 square miles (deterimined by West Virginia Development Co.).

RECORDS AVAILABLE.—October 13, 1911, to September 30, 1917.

GAGE.—Chain gage attached to upstream side of bridge; read by French Shaffer.

DISCHARGE MEASUREMENTS.—Made from bridge or by wading.

CHANNEL AND CONTROL.—Coarse gravel and stones.

EXTREMES OF STAGE.—Maximum stage recorded during year, 8.37 feet at 7 a. m. March 12; minimum stage, 1.49 feet at 5 p. m. October 15.

1911–1917: Extremes of stage are those recorded above.

Maximum flood occurred July 10, 1888, stage unknown.

ICE.—Stage-discharge relation probably affected by ice during extremely cold weather.

ACCURACY.—Station was first visited by engineers of the Survey in March, 1916. Discharge measurements made at gage heights 3.42 and 4.27 during these visits plot respectively 17 and 30 per cent below rating curve used from 1911 to 1914. Monthly discharge for 1914 as published in Water-Supply Paper 383 probably as accurate as indicated. Discharge data subsequent to 1914 withheld for additonal information. Gage read twice daily to tenths to April 1, then to hundredths. Gage readings probably affected by ice January 17 to February 20. Records good.

COOPERATION.—Station maintained and records furnished by the Hydro-Electric Co. of West Virginia.

The following discharge measurement was made by Peterson and Hopkins: September 24: Gage height, 1.64 feet, discharge, 9.1 second-feet.

Daily gage height, in feet, of Blackwater River at Hendricks, W. Va., for the year ending Sept. 30, 1917.

SHAVERS FORK AT PARSONS, W. VA.

Location.—At steel highway bridge 600 feet northwest of railroad station at Parsons, Tucker County, and half a mile above confluence with Dry Fork.

Drainage area.—210 square miles (determined by Pittsburgh Flood Commission).

Records available.—October 14, 1910, to September 30, 1917.

Gage.—Standard chain gage attached to bridge, read by R. W. Evans. Sea-level elevation of zero of gage, 1,631.70 feet.

Discharge measurements.—Made from downstream side of bridge or by wading.

Channel and control.—Channel rocky. Control, coarse gravel and rocks; probably permanent.

Extremes of discharge.—Maximum stage recorded during year, 9.90 feet at 8 a. m. March 12 (discharge, 12,300 second-feet); minimum stage, 2.15 feet September 8 (discharge, 3 second-feet).

High waters of 1868 and 1907 reached a stage represented by approximately 12.5 feet, referred to present gage datum.

Ice.—Stage-discharge relation affected by ice during severe winters.

Regulation.—The flow at low stages may be affected by the storage of water at a pulp mill dam about three-fourths mile above the station.

ACCURACY.—Stage-discharge relation practically permanent, affected by ice December 13–20, and February 6–16. A discharge measurement made in September, 1917, indicated a change in the stage-discharge relation below 300 second-feet. It was assumed that the change in relation occurred during the high water of March. Rating curve used to March 11, and curve used March 12 to September 30, well defined between 40 and 10,000 second-feet; beyond these limits curve is an extension. Gage read twice daily to tenths. Daily discharge ascertained by applying mean daily gage heights to rating table. Results good except for periods affected by ice, for which they are poor.

The following discharge measurement was made by Peterson and Hopkins: September 24: Gage height 2.82 feet, discharge, 48 second-feet.

Daily discharge, in second-feet, of Shavers Fork at Parsons, W. Va., for the year ending Sept. 30, 1917.

BIG SANDY CREEK AT ROCKVILLE, W. VA.

Location.—At the highway bridge at Rockville, in Preston County, about 5 miles above mouth of creek and 6 miles below Bruceton Mills.

Drainage area.—202 square miles (determined by West Virginia Development Co.).

Records available.—May 7, 1909, to September 30, 1917.

Gage.—Chain gage attached to downstream side of bridge; read by A. A. Christopher and Levi Zweyer.

Discharge measurements.—Made from bridge or by wading.

Channel and control.—Channel bed consists of boulders and bed rock. Control practically permanent.

Extremes of discharge.—Maximum stage recorded during year, 14.98 feet at 6 a. m. January 22 (discharge about 17,500 second-feet); minimum stage, 3.10 feet October 9 (discharge, 8.1 second-feet).

Ice.—Stage-discharge relation affected by ice during periods of extremely cold weather.

Regulation.—Gristmills at Rockville, Clifton Mills, and Bruceton Mills operated by water power, may produce fluctuations in stage during low water.

Accuracy.—Stage-discharge relation practically permanent. Affected by ice December 13–20 and probably to some extent during parts of January and February. Rating curve well defined between 10 and 8,000 second-feet; beyond these limits curve is an extension. Gage read twice daily to tenths. Daily discharge ascertained by applying mean daily gage heights to rating table. Results good except for periods affected by ice for which they are poor.

Daily discharge, in second-feet, of Big Sandy Creek at Rockville, W. Va., for the year ending Sept. 30, 1917.

LITTLE BEAVER RIVER BASIN.

LITTLE BEAVER RIVER NEAR EAST LIVERPOOL, OHIO.

LOCATION.—At steel highway bridge known as Grimms Bridge, about 4 miles above mouth of river and about 4 miles northeast of East Liverpool, Columbiana County. North Fork enters river on left about 3 miles above station.

DRAINAGE AREA.—505 square miles (measured on topographic maps).

RECORDS AVAILABLE.—May 17, 1915, to September 30, 1917.

GAGE.—Chain gage fastened to downstream side of highway bridge; read by C. W. Garn.

DISCHARGE MEASUREMENTS.—Made from bridge or by wading.

CHANNEL AND CONTROL.—One channel at all stages; at extremely high stages water flows around both bridge abutments. Channel straight for 100 feet above and 300 feet below station. Rapids about 600 feet below bridge act as primary control, probably permanent. Point of zero flow, gage height, 0.1±0.2 foot.

EXTREMES OF STAGE.—Maximum stage recorded during year, 9.25 feet at 5.00 p. m. January 5; minimum stage, 2.07 feet at 7 a. m. September 26. Highest known flood reached a stage represented by gage height about 20 feet.

ICE.—Stage-discharge relation affected by ice and by ice jams.

ACCURACY.—Stage-discharge relation probably permanent; affected by ice December 14–26, January 12–21, and February 2 to March 1. Data inadequate for determining rating curve. Gage read twice daily to hundredths. Records excellent.

COOPERATION.—Station maintained in cooperation with United States Engineer Corps.

Daily gage height, in feet, of Little Beaver River near East Liverpool, Ohio, for the year ending Sept. 30, 1917.

YELLOW CREEK BASIN.

YELLOW CREEK AT HAMMONDSVILLE, OHIO.

LOCATION.—At covered highway bridge on Steubenville pike about one-fifth mile southwest of Hammondsville, Jefferson County. North Fork enters on left 1,000 feet below station.

DRAINAGE AREA.—169 square miles (measured on topographic maps).

RECORDS AVAILABLE.—May 13, 1915, to September 30, 1917.

GAGE.—Chain gage on downstream side of bridge about 25 feet from left end; read by W. J. Sprague.

DISCHARGE MEASUREMENTS.—Made from bridge or by wading.

CHANNEL AND CONTROL.—One channel, but at extreme high stages, stream flows around both abutments; straight 1,000 feet above and curved 100 feet below station. Control practically permanent. Point of zero flow, gage height about 1.4 feet September, 1915, and 1916, and October, 1917.

EXTREMES OF STAGE.—Maximum stage recorded during year, 8.63 feet at 4.30 p. m. January 5; minimum stage recorded 1.80 feet at 5 p. m. October 8.

Highest known flood reached a stage represented by gage height about 16 feet.

ICE.—Stage-discharge relation affected by ice during severe winters.

ACCURACY.—Stage-discharge relation practically permanent; affected by ice December 18-27 and February 2-27. Data inadequate for determining rating curve. Gage read twice daily to hundredths. Records excellent.

COOPERATION.—Station maintained in cooperation with United States Engineer Corps.

Daily gage height, in feet, of Yellow Creek at Hammondsville, Ohio, for the year ending Sept. 30, 1917.

MIDDLE ISLAND CREEK BASIN.

MIDDLE ISLAND CREEK AT LITTLE, W. VA.

Location.—At highway bridge at Little, about 6 miles southeast of Friendly, Tyler County. Stewart Run enters on left about 500 feet below station.

Drainage area.—458 square miles (measured on topographic maps).

Records available.—May 7, 1915, to September 30, 1917.

Gage.—Vertical and inclined staff on left bank immediately below the bridge; read by J. R. Bowles.

Discharge measurements.—Made from bridge or by wading. Stay wire is used for measurements at high stages.

Channel and control.—One channel at all stages; straight for about 400 feet above and 250 feet below station. Primary control is at foundation of old mill dam 250 feet below station; composed of bed rock, foundation timbers, small deposit of rock and sand; probably permanent. Point of zero flow, gage height 1.4 feet ± 0.2 foot.

Extremes of stage.—Maximum stage recorded during year, 22.22 feet at 5 p. m. January 22; minimum stage, 1.90 feet at 6 p. m. August 22.

Highest flood known occurred in August, 1875; gage height about 33.5 feet.

Ice.—Stage-discharge relation affected by ice during winter months.

Accuracy.—Stage-discharge relation practically permanent; affected by ice February 3–18. Gage not checked since August, 1916; therefore record of daily discharge is withheld. Gage read twice daily to hundredths.

Cooperation.—Base data furnished by United States Engineer Corps.

Discharge measurements of Middle Island Creek at Little, W. Va., during the year ending Sept. 30, 1917.

LITTLE MUSKINGUM RIVER BASIN.

LITTLE MUSKINGUM RIVER AT FAY, OHIO.

Location.—About a mile northwest of Fay, Washington County, Ohio, 7 miles from St. Marys, W. Va., and 12 miles from Marietta, Ohio. Bear Run enters on left about half a mile above station. Covered highway bridge crosses river just above Bear Run.

Drainage area.—259 square miles (measured on topographic maps).

Records available.—May 14, 1915, to September 30, 1917.

Gage.—Inclined and vertical staff on right bank about 400 feet below suspension footbridge; read by G. I. Smith.

Discharge measurements.—Made from suspension bridge or by wading.

Channel and control.—One channel at all stages; straight several hundred feet above and below bridge. Overflow at gage height about 13 feet; wide overflow at maximum stages. Bed of stream mud, sand, rock, and gravel; primary control at ford 50 feet below gage compact sand and gravel; fairly permanent. Point of zero flow, gage height 0.7±0.2 foot May, 1915.

EXTREMES OF STAGE.—Maximum stage recorded during the year, 21.5 feet at 5 p. m. January 22; minimum stage, 1.19 feet at 8 a. m. September 27.

Highest flood known reached a stage represented by gage height about 23 feet.

ICE.—Stage-discharge relation affected by ice in severe winters.

ACCURACY.—Stage-discharge relation probably permanent; probably affected to some extent by ice. Data inadequate for determining rating curve. Gage read twice daily to hundredths. Records excellent.

COOPERATION.—Base data furnished by United States Engineer Corps.

Discharge measurements of Little Muskingum River at Fay, Ohio, during the year ending Sept. 30, 1917.

[Made by U. S. Army Engineers.]

MUSKINGUM RIVER BASIN.

MUSKINGUM RIVER AT FRAZIER, OHIO.

LOCATION.—At highway bridge at Frazier, Muskingum County, 4½ miles below Zanesville. Brush Creek enters on right about one-third mile below the gage.

DRAINAGE AREA.—6,980 square miles (United States Engineer Corps).

RECORDS AVAILABLE.—June 1, 1915, to September 30, 1917.

GAGE.—Staff near upper corner of right abutment of bridge; read by D. A. Burns. Sea-level elevation of zero of gage, 663.29 feet.

DISCHARGE MEASUREMENTS.—Made from upstream side of bridge or by wading on crest of dam No. 9, about 5½ miles below gage. Leakage past dam, through lock and power plants, should be included with flow over crest.

CHANNEL AND CONTROL.—River straight above and below. Control is crest of dam No. 9, about 5½ miles below gage. Except for leakage through lock and dam and leakage and flow through power plants at the dam, the gage height of the crest of the dam, 9.0 feet, is the point at which flow would be zero.

EXTREMES OF STAGE.—Maximum mean daily stage recorded during year, 18.25 feet March 14; minimum stage, 9.3 feet September 21–30.

Flood of March, 1913, reached a stage of 49.1 feet; highest stage ever recorded.

ICE.—Stage-discharge relation affected by ice jams at times.

REGULATION.—Leakage through the lock and the power plants at dam No. 9 and the operation of power plants at dams Nos. 9 and 10 may affect the low-water flow to some extent.

ACCURACY.—Stage-discharge relation permanent, except as the relation may be affected by leakage through dam No. 9, through the gates of the power plants and through the lock, and by the operation of the power plants at dam No. 9; probably not affected by ice. The flow from the area between the measuring section and the crest of dam No. 9 may be sufficient at times to affect the stage-discharge relation. This area, however, is small, and such conditions would be of rare occurrence and of small effect. Gage read twice daily to tenths. Records good.

COOPERATION.—Base data furnished by the United States Engineer Corps.

Discharge measurements of Muskingum River at Frazier, Ohio, during the year ending Sept. 30, 1917.

MUSKINGUM RIVER AT BEVERLY, OHIO.

LOCATION.—At Lock 4 at Beverly, Washington County. Wolf Creek enters on right immediately above station.

DRAINAGE AREA.—7,700 square miles (United States Engineer Corps).

RECORDS AVAILABLE.—June 1, 1915, to September 30, 1917.

GAGE.—Ceramic tile gage, graduated to tenths of a foot, on lower buttress of river wall of Lock 4, about 1,000 feet above the measuring section. Sea-level elevation of zero of gage, 602.60 feet (United States Engineer Corps).

DISCHARGE MEASUREMENTS.—Made from upstream side of highway bridge 1,000 feet below gage.

CHANNEL AND CONTROL.—Bed of stream gravel and masonry débris of old bridge piers; probably permanent. Stream curves slightly to the left from 1,000 feet above to 1,000 feet below the section. Control is crest of dam No. 3, 10.8 miles below. At gage height 5.2 feet or crest of dam No. 3, flow would be zero provided there was no leakage through dam, lock, or power plant at dam.

EXTREMES OF STAGE.—Maximum mean daily stage recorded during year, 20.3 feet April 6; minimum stage, 3.0 feet October 1–13.

Flood of March, 1913, reached a stage of 46.55, the highest stage ever recorded.

ICE.—Stage-discharge relation not affected by ice.

REGULATION.—Leakage through dam No. 3, lock, and the power plant at the dam may affect the low-water flow to some extent.

ACCURACY.—Stage-discharge relation practically permanent; not affected by ice. Dam No. 3, about 11 miles below, the control for the gage, leaks so that the water falls below the crest during low water. Change in this leakage, leakage and flow through the power plant, leakage through lock, and inflow into pool 3 below the measuring section may all affect the stage-discharge relation at low and medium stages. When the stage of the Ohio at Marietta is about 39 feet or more, the stage-discharge relation is affected by backwater. Records of daily discharge withheld for additional information. Gage read twice daily to tenths. Records good, except as may be affected by described conditions at low and medium stages.

COOPERATION.—Base data furnished by United States Engineer Corps.

Daily gage height, in feet, of Muskingum River at Beverly for the year ending Sept. 30, 1917.

LITTLE KANAWHA RIVER BASIN.

LITTLE KANAWHA RIVER AT GLENVILLE, W. VA.

Location.—At three-span steel highway bridge at Glenville, Gilmer County. Stewart Creek enters on right about 1½ miles above station.

Drainage area.—385 square miles (measured on topographic maps).

Records available.—June 1, 1915, to September 30, 1917.

Gage.—Vertical and inclined staff attached to upstream side of right pier of bridge; read by Hollie Gainor. Gage was established by the United States Weather Bureau September 10, 1900 (read daily to tenths at 8 a. m.), repaired and its datum lowered 2.5 feet on June 1, 1915.

Discharge measurements.—Made from bridge or by wading.

Channel and control.—One channel at all stages; straight for 100 feet above and 150 feet below station. Bed of river composed of mud, rock, sand, and gravel; control is probably fairly permanent. Point of zero flow, gage height about 1.0 foot June and September, 1915.

Extremes of stage.—Maximum stage recorded during year, 28.3 feet at 7.15 a. m. January 22; minimum stage, 1.50 feet September 21 and 27.

Highest flood known reached a stage represented by gage height about 29 feet, referred to present datum.

Ice.—Stage-discharge relation affected by ice during severe winters.

Accuracy.—Stage-discharge relation probably permanent; probably not affected by ice. Data inadequate for determining rating curve. Gage read twice daily to hundredths. Records excellent.

Cooperation.—Base data furnished by United States Engineer Corps.

Discharge measurements of Little Kanawha River at Glenville, W. Va., during the year ending Sept. 30, 1917.

[Made by F. Conklin.]

LITTLE KANAWHA RIVER AT LOCK 4, PALESTINE, W. VA.

Location.—At Lock 4, Palestine, Wirt County, 30 miles from Parkersburg via Little Kanawha Railroad. Reedy Creek enters on left 1 mile above gage.

Drainage area.—1,500 square miles (measured on map of West Virginia, scale 1:500,000).

Records available.—April 25, 1915, to September 30, 1917. The upper and lower gages at the lock have been read under the direction of the Corps of Engineers, United States Army, as follows: November 5, 1905, to July 14, 1906; September 1-30, 1906; October 25, 1906, to date.

Gage.—Upper gage at lock; vertical staff on right bank bolted to right side of river wall of lock just above upper gates; an inclined section of gage extends above top of lock wall; read by James Burton, lockmaster.

Discharge measurements.—Made at cable about 1,200 feet below gage or by wading on crest of dam.

Channel and control.—One channel at all stages. Crest of dam No. 4 is the control for the gage; lowest point in crest of dam is at 9.4 feet gage height, which is the point of zero flow except for leakage through dam, lock gates and valves. Backwater submerges dam No. 4 during extreme floods on Ohio River.

Extremes of stage.—Maximum stage recorded during year, 21.9 feet at 8 a. m. January 22; minimum stage, 9.48 feet at 6 p. m. September 20.

Highest headwater as reported by lockmaster occurred in 1897, and was equivalent to a gage height of about 30 feet on the lower gage, which corresponds to a reading of about 24.4 on upper gage, assuming 1 foot fall at dam. Highest backwater was during the flood of 1913, when crest was at 19.2 feet on upper gage.

Ice.—Stage-discharge relation probably not affected by ice.

Regulation.—Flow may be affected at times by the manipulation of the pool above dam No. 5, about 9.5 miles above dam No. 4, and the occasional use of flash boards on dam No. 4.

Accuracy—Stage-discharge relation practically permanent; not affected by ice during year. Variable leakage through lock and dam may affect the stage-discharge relation at low stages. Data inadequate for determining daily discharge. Gage read twice daily to hundredths. Previous to April 25, 1915, gage read once daily to tenths. Records excellent.

Cooperation.—Base data furnished by United States Engineer Corps.

Discharge measurements of Little Kanawha River at Lock 4, Palestine, W. Va., during the year ending Sept. 30, 1917.

[Made by U. S. Army Engineers.]

SOUTH FORK OF HUGHES RIVER AT MACFARLAN, W. VA.

Location.—About 80 feet above highway bridge half a mile east of Macfarlan, Ritchie County. Dutchman Run enters river on left 3,000 feet below station.

Drainage area.—210 square miles (measured on topographic maps).

Records available.—May 17, 1915, to September 30, 1917.

Gage.—Vertical staff on right bank; read by A. H. Reynolds.

Discharge measurements.—Made from bridge or by wading.

Channel and control.—One channel at all stages; straight 300 feet above and 1,500 feet below bridge. Bed of stream rock and mud. Control probably fairly permanent.

Extremes of stage.—Maximum stage recorded during the year, 25.7 feet at 8 a. m. January 22; minimum stage, 1.90 feet October 4–8.

Highest flood known reached a stage represented by gage height about 29 feet.

Ice.—Stage-discharge relation affected by ice during severe winters.

Accuracy.—Stage-discharge relation practically permanent; probably affected by ice part of February. Rating curve well defined between 100 and 2,660 second-feet and fairly well defined at other stages. Gage read twice daily to hundredths. Record of daily discharge withheld because gage was not checked during 1917.

Cooperation.—Base data furnished by United States Engineer Corps.

Daily gage height, in feet, of South Fork of Hughes River at Macfarlan, W. Va., for the year ending Sept. 30, 1917.

HUGHES RIVER AT CISKO, W. VA.

Location.—At Cisko, about 1 mile below junction of North and South forks and 6 miles south of Petroleum, Ritchie County.

Drainage area.—453 square miles (measured on topographic maps).

Records available.—May 29, 1915, to September 30, 1917.

Gage.—Vertical and inclined staff on right bank; read by S. J. Enoch.

Discharge measurements.—Made from cable 40 feet below gage or by wading at the same section.

Channel and control.—One channel at all stages; straight for about 150 feet above and 500 feet below cable section. Bed of river is sand, gravel, mud, and boulders; control is probably permanent.

Extremes of stage.—Maximum stage recorded during year, 30.25 feet at 3 p. m. January 22; minimum, 2.14 feet October 14 and 15.

Highest known flood previous to January, 1917, reached a stage represented by gage height about 30 feet.

Ice.—Stage-discharge relation affected by ice during winter months.

Accuracy.—Stage-discharge relation probably permanent; probably affected by ice December, January, and February. Stages of Ohio River at Parkersburg of about 40 feet or more will probably cause backwater at the gage. Records of daily discharge withheld because gage has not been checked since installation. Gage read twice daily to hundredths. Records excellent except for possible errors in gage.

Cooperation.—Base data furnished by United States Engineer Corps.

Discharge measurements of Hughes River at Cisko, W. Va., during the year ending Sept. 30, 1917.

[Made by U. S. Army Engineers.]

HOCKING RIVER BASIN.

HOCKING RIVER AT ATHENS, OHIO.

Location.—At single-span highway bridge at Mill Street, about three-fourths of a mile from business section of Athens, Athens County. Margaret Creek enters on right, 3½ miles above station.

Drainage area.—944 square miles (measured on topographic maps).

Records available.—May 3, 1915, to September 30, 1917.

Gage.—Vertical and inclined staff at downstream end of right abutment; read by Paul B. Casley.

Discharge measurements.—Made from bridge or by wading.

Channel and control.—Channel straight about 700 feet above and below station. Left bank overflows at gage height 17 feet and water passes around bridge. Bed of stream rocky with sand deposits near both banks. Ruins of old mill dam 300 feet below gage act as control. Stage-discharge relations will shift as dam decays.

Extremes of discharge.—Maximum stage recorded during year, 16.4 feet at 8 a. m. January 23 (discharge, 10,900 second-feet); minimum stage, 2.80 feet several days in October (discharge, 65 second-feet).

Highest flood known reached a stage represented by gage height about 26 feet.

Ice.—Stage-discharge relation probably not materially affected by ice except during extremely cold weather.

Accuracy.—Stage-discharge relation practically permanent; affected by ice December 18–19, January 14–20, and February 15–17. Rating curve well defined to 12,000 second-feet; above this point curve is an extension. Gage read twice daily to hundredths. Daily discharge obtained by applying mean daily gage height to rating table except for periods affected by ice. Records excellent.

Cooperation.—Base data furnished by United States Engineer Corps.

Daily discharge, in second-feet, of Hocking River at Athens, Ohio, for the year ending Sept. 30, 1917.

KANAWHA RIVER BASIN.

NEW RIVER AT EGGLESTON, VA.

LOCATION.—At highway bridge at Eggleston, Giles County.

DRAINAGE AREA.—2,920 square miles.

RECORDS AVAILABLE.—October 1, 1914, to September 30, 1917.

GAGE.—Chain gage attached to downstream side of bridge, read by J. A. Bishop.

DISCHARGE MEASUREMENTS.—Made from upstream side of bridge.

CHANNEL AND CONTROL.—Stream bed composed of rock covered with silt. Primary control is rock ledge about 1¼ miles below gage.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 11.86 feet at 8 a. m.; March 5 (discharge, 28,400 second-feet); minimum stage, 2.37 feet at 5 p. m., August 29 (discharge, 652 second-feet). The flood of 1878 reached a stage of about 40 feet on present gage.

ICE.—Stage-discharge relation affected by ice during severe winters.

ACCURACY.—Stage-discharge relation practically permanent; see foot-notes to tables of daily discharge for effect of ice. Rating curve well defined between 1,200 and 45,000 second-feet; extended beyond these limits. Gage read twice daily to hundredths. Daily discharge ascertained by applying mean daily gage height to rating table, except as noted. Records excellent.

Discharge measurements of New River at Eggleston, Va., during the year ending Sept. 30. 1917.

NOTE.—Daily discharge estimated, because of ice, from observer's notes, climatic data, and by comparison with discharge at Radford as follows: 1914–15, Dec. 15–30; 1915–16, Dec. 14–18, and Jan. 19–20; 1916–17, Dec. 10–31, Feb. 2–16. Daily discharge Oct. 1–20, 1915, estimated from flow at Radford. Determinations of daily and monthly discharge for 1914–15 differ slightly from those published in Water Supply Paper No. 423, owing to revision of rating curve. Braced figures show mean discharge for period included.

Monthly discharge of New River at Eggleston, Va., for the years ending Sept. 30, 1915–1917.

Month.	Discharge in second-feet.				Run-off (depth in inches on drainage area).

KANAWHA RIVER AT LOCK 2, MONTGOMERY, W. VA.

Location.—At Lock 2, three-fourths of a mile below Chesapeake & Ohio Railway station at Montgomery, Fayette County. Morris Creek enters on left about 300 feet below the gage.

Drainage area.—8,470 square miles.

Records available.—June 22, 1915, to September 30, 1917. Upper and lower gages at the lock have been read since December, 1887, under the direction of the Corps of Engineers, United States Army.

Gage.—Upper gage at lock, vertical and inclined staff on right bank, short distance above upper lock gates; vertical section fastened to land wall of lock, inclined section at upstream end of paved slope; read by George Meyers, lockmaster. A chain gage fastened to downstream handrail near center of toll bridge at Montgomery is used in referring water surface at bridge when making discharge measurements.

Discharge measurements.—Made from bridge at Montgomery or by wading on the crest of the dam.

Channel and control.—One channel at all stages; straight for 300 feet above and 800 feet below bridge. Bed of river composed of rock, sand, and mud. The dam at Lock No. 2 is control for all stages, as there is a fall of about 2 feet at the dam at the maximum stage. Except for the leakage through the dam and lock, point of zero flow is at lowest point in crest of dam, which is 17.9 feet above zero of upper gage.

Extremes of discharge.—Maximum stage recorded during year, 36.8 feet at 7 a. m. March 5 (discharge, 138,000 second-feet); minimum stage, 18.40 feet at 7 a. m. September 1 (discharge, 1,270 second-feet).

Highest stage recorded occurred May 23, 1901, at 6 a. m.; upper gage 49.65 lower gage 47.70 (discharge, about 250,000 second-feet).

Ice.—Stage-discharge relation not affected by ice.

Leakage.—At about gage height 19 feet on upper gage, leakage through the dam amounts to about 500 second-feet. Leakage through the lock gates amounts to about 110 and 260 second-feet, depending upon which of the two gates is closed.

Accuracy.—Stage-discharge relation practically permanent except as may be affected by change in leakage through lock and dam; not affected by ice. Rating curve well defined throughout. Gage read twice daily to hundredths since June 22, 1915; once daily previous to this date. Daily discharge ascertained by applying mean daily gage height to rating table which is adjusted for leakage through dam and lock gates. Records good.

Cooperation.—Base data furnished by United States Engineer Corps.

Discharge measurements of leakage through gates at Lock 2, Kanawha River, Montgomery, W. Va., during the year ending Sept. 30, 1917.

[Made by Peterson and Hopkins.]

Date.		Gage height.	Discharge.
		Feet.	*Sec.-ft.*
Sept. 18	Upper gates	18.91	263
18	Lower gates	19.04	106

Discharge measurements of Kanawha River at Lock 2, Montgomery, W. Va., during the year ending Sept. 30, 1917.

[Made by Peterson and Hopkins.]

Date.	Gage height.	Discharge.
	Feet.	*Sec.-ft.*
Sept. 17	18.96	1,980
18	18.93	[a] 1,490

[a] Measured on crest of dam No. 2; does not include leakage through dam but does include leakage of 263 second-feet through lock.

Daily discharge, in second feet, of Kanawha River at Lock 2, Montgomery, W. Va., for the year ending Sept. 30, 1917.

GREENBRIER RIVER AT ALDERSON, W. VA.

Location.—At reinforced concrete arch highway bridge at Alderson, Monroe County, half a mile above mouth of Muddy Creek.

Drainage area.—1,340 square miles.

Records available.—July 30, 1895, to July 15, 1906; May 10, 1907, to September 30, 1917.

Gage.—Chain gage attached to downstream side of bridge near center of second span from left side of river. Read by W. J. Hancock.

Discharge measurements.—Made from bridge or by wading.

Channel and control.—The channel and control are composed of coarse gravel and are practically permanent.

Extremes of discharge.—Maximum stage recorded during year, 14.2 feet at 6 p. m. March 4 (discharge, 34,000 second-feet); minimum stage, 1.60 feet August 31 (discharge, 74 second-feet). Maximum stage since establishment of station, 19.4 feet at 6 p. m. March 27, 1913 (discharge, about 62,000 second-feet).

Ice.—Stage-discharge relation occasionally affected by ice for short periods during severe winters.

Accuracy.—Stage-discharge relation practically permanent; affected by ice December 12–14 and February 12 and 13. Rating curve used during 1915, 1916, and 1917, fairly well defined between 100 and 28,000 second-feet; extended beyond these limits. Gage read twice daily to hundredths. Daily discharge ascertained by applying mean daily gage heights to rating table. Discharge December 12–14, 1917, interpolated because of ice conditions. Records good except for ice periods, for which they are poor.

Discharge measurements of Greenbrier River at Alderson, W. Va., during the year ending Sept. 30, 1917.

[Made by B. E. Jones.]

LITTLE COAL RIVER AT McCORKLE, W. VA.

Location.—At McCorkle, Lincoln County, on Coal River branch of Chesapeake & Ohio Railway. Cobb Creek enters river on left about 400 feet below station.

Drainage area.—375 square miles (measured on topographic maps).

Records available.—July 23, 1915, to September 30, 1917.

Gage.—Vertical and inclined staff on left bank just below McCorkle Hotel; read by F. M. Priestly.

Discharge measurements.—Made from cable 40 feet above inclined section of gage or by wading.

Channel and control.—One channel at all stages; slightly curved above and below cable section. Bed of stream composed of loose sand; but control is probably fairly permanent. Flow of Cobb Creek affects stage at gage and should be included in station.

Extremes of discharge.—Maximum stage recorded during year, 13.0 feet at 5 p. m. March 3 (discharge about 8,000 second-feet); minimum stage, 1.50 feet October 6, 7, 8, and September 7 (discharge, .3 second-feet).

Highest known flood August 9, 1916, reached a stage of 28.57 feet (discharge, roughly, 24,000 second-feet).

Ice.—Stage-discharge relation not affected by ice to any extent during record.

Accuracy.—Stage-discharge relation practically permanent, changed by record flood of August, 1916. Rating curve used to August 10, 1916, well defined between 43 and 4,000 second-feet; curve used after this date well defined between 43 and 5,500 second-feet; both curves extended beyond limits noted. Gage read twice daily to hundredths. Daily discharge ascertained by applying mean daily gage height to rating table. Records good.

Discharge measurements of Little Coal River at McCorkle, W. Va., during the year ending Sept. 30, 1917.

[Made by F. Conklin.]

RACCOON CREEK BASIN.

RACCOON CREEK AT ADAMSVILLE, OHIO.

Location.—About 200 feet above covered highway bridge at Adamsville, Gallia County, 5 miles southwest from Hocking Valley Railroad station at Bidwell. Indian Creek enters on right 1¼ miles above station.

Drainage area.—537 square miles (measured on topographic maps).

Records available.—June 25, 1915, to September 30, 1917.

Gage.—Vertical and inclined staff on left bank 200 feet above bridge; read by Irene Call

Discharge measurements.—Made from covered highway bridge or by wading.

Channel and control.—Straight for about 500 feet above and 600 feet below bridge. Bed of stream composed of mud, sand, and gravel. Principal control at ruins of old mill dam 1,200 feet below bridge; probably permanent.

Extremes of discharge.—Maximum stage recorded during year, 17.9 feet March 14 (discharge, 6,300 second-feet); minimum stage recorded, 1.75 feet at 7 a. m. September 26 (discharge, 18 second-feet).

High-water marks indicate maximum stage of about 24.5 feet.

Ice.—Stage-discharge relation affected by ice during severe winters.

Accuracy.—State-discharge relation practically permanent; affected by ice December 15–21, February 5–13, and probably to some extent January 16–20. Rating curve well defined between 70 and 5,800 second-feet; beyond these limits, the curve is an extension. Gage read twice daily to hundredths. Daily discharge ascertained by applying mean daily gage height to rating table, except for ice periods, for which it is estimated from climatic data. Open-water records excellent; ice records poor.

Cooperation.—Base data furnished by United States Engineer Corps.

Daily discharge, in second-feet, of Raccoon Creek at Adamsville, Ohio, for the year ending Sept. 30, 1917.

GUYANDOT RIVER BASIN.

GUYANDOT RIVER AT WILBER, W. VA.

LOCATION.—At site of Hutchinson Lumber Co.'s suspension bridge at Wilber, three-fourths mile below Manbar, Logan County. Rich Creek enters river on left about 600 feet above station.

DRAINAGE AREA.—791 square miles (measured on map of West Virginia, scale 1:500,-000).

RECORDS AVAILABLE.—July 13, 1915, to September 30, 1917.

GAGE.—Vertical and inclined staff on right bank; read by Allie Smith. Vertical section fastened to downstream corner of right timber crib pier; inclined section is about 10 feet downstream.

DISCHARGE MEASUREMENTS.—Made from cable installed between towers of former bridge in February, 1916, or by wading.

CHANNEL AND CONTROL.—Straight for about 1,000 feet above and 500 feet below station. Bed of river composed of solid rock, boulders, and mud; control probably permanent. Point of zero flow, gage height 0.00 ± 0.5 foot.

EXTREMES OF STAGE.—Maximum stage recorded, 17.0 feet at 5 p. m. March 4; minimum, 1.10 feet September 26.

Highest flood known reached a stage represented by gage height about 24 feet.

ICE.—Stage-discharge relation probably not affected by ice except in severe winters.

ACCURACY.—Stage-discharge relation probably permanent; probably affected by ice to some extent during December and February. Rating curve not yet determined. Gage read twice daily. Records excellent.

COOPERATION.—Base data furnished by United States Engineer Corps.

Daily gage height, in feet, of Guyandot River at Wilber, W. Va., for the year ending Sept. 30, 1917.

GUYANDOT RIVER AT BRANCHLAND, W. VA.

Location.—At highway bridge at Branchland, Lincoln County. Fourmile Creek enters river on left about 20 feet above bridge.

Drainage area.—1,230 square miles (measured on map of West Virginia, scale 1:500,000).

Records available.—July 8, 1915, to September 30, 1917.

Gage.—Chain gage fastened to handrail on upstream side of bridge near center of main span; read by John A. Broaddus.

Discharge measurements.—Made from bridge or by wading.

Channel and control.—Bed of stream is composed of rock, gravel, sand, and mud and is fairly permanent; character of control not determined.

Extremes of discharge.—Maximum stage recorded during year, 31.3 feet at noon March 5 (discharge, about 30,000 second-feet); minimum, 2.76 feet August 21 (discharge, about 53 second-feet).

Highest flood known reached a gage height of about 44 feet by present gage.

Ice.—Stage-discharge relation affected by ice during cold winters.

Accuracy.—Stage-discharge relation may change during floods; affected by ice December 14–20, February 6–16. Rating curve well defined between 280 and 25,000 second-feet; beyond these limits the curve is an extension. Gage read twice daily to hundredths. Daily discharge ascertained by applying mean daily gage height to rating table except for periods affected by ice or missing gage readings. Records good except those estimated, which are poor.

Cooperation.—Base data furnished by United States Engineer Corps.

Discharge measurements of Guyandot River at Branchland, W. Va., during the year ending Sept. 30, 1917.

[Made by F. Conklin.]

MUD RIVER AT YATES, W. VA.

LOCATION.—About 200 feet above highway bridge at Yates, Cabell County, 2 miles above Howell mill dam, and 15 miles from Huntington.

DRAINAGE AREA.—318 square miles (measured on topographic maps).

RECORDS AVAILABLE.—July 19, 1915, to September 30, 1917.

GAGE.—Vertical and inclined staff on left bank, read by C. J. McDonie.

DISCHARGE MEASUREMENTS.—Made from single-span steel highway bridge below gage.

CHANNEL AND CONTROL.—One channel up to high stages, when right bank overflows around right abutment; straight for about 50 feet above and 75 feet below bridge. Primary control at ford, about 100 feet below gage; fairly permanent.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 16.80 feet at 5 p. m. March 14 (discharge, 5,980 second-feet); minimum is not definitely known as sandbar formed around gage during low water period.

Highest flood known reached a gage height of about 23 feet by present gage.

ICE.—Stage-discharge relation affected by ice during severe winters.

ACCURACY.—Stage-discharge relation probably permanent; affected by ice January 14–20 and February 3–11. Rating curve well defined between 14 and 5,500 second-feet; extended beyond these limits. Gage read twice daily to hundredths. Daily discharge ascertained by applying mean daily gage height to rating table, except during periods stage-discharge relation was affected by ice. Records good except for periods for which discharge was estimated on account of ice or missing gage readings, for which they are poor.

COOPERATION.—Base data furnished by United States Engineer Corps.

Discharge measurements of Mud River at Yates, W. Va., during the year ending Sept. 30, 1917.

[Made by F. Conklin.]

TWELVEPOLE CREEK BASIN.

TWELVEPOLE CREEK AT WAYNE, W. VA.

LOCATION.—At highway bridge, 500 feet above railroad bridge of East Lynne branch of Norfolk & Western Railway at Wayne, Wayne County, about three-fourths mile below junction of East and West forks.

DRAINAGE AREA.—291 square miles (measured on topographic maps).

RECORDS AVAILABLE.—July 1, 1915, to September 30, 1917.

GAGE.—Chain gage attached to upstream handrail about 90 feet from left abutment; read by Bryon Smith.

DISCHARGE MEASUREMENTS.—Made from highway bridge or by wading.

CHANNEL AND CONTROL.—Straight for about 80 feet above and 1,200 feet below bridge. Bed of stream composed of rock and sand. Principal control is Sampson's milldam; probably permanent, but at low stages the operation of the mill may affect the discharge relation.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 15.25 feet at 8.30 a. m. January 22 (discharge, 5,140 second-feet); minimum, 1.18 feet August 2, 8, and 29 (discharge, about 5 second-feet).

Highest flood known reached a stage represented by gage height about 25 feet.

ICE.—Stage-discharge relation probably not materially affected by ice.

REGULATION.—None, except for backwater caused during low water periods by operation of small power plant at Sampson's mill about a mile below gage.

ACCURACY.—Stage-discharge relation probably permanent; slightly affected by ice January 14–20 and February 3–11. Operation of power plant at dam about a mile below gage may have slight effect upon stage-discharge relation at low stages, but this effect, if any, is small as the plant is only operated occasionally for a few hours at a time. Rating curve well defined beween 139 and 6,700 second-feet, fairly well defined between 29 and 139 second-feet; extended beyond these limits. Gage read twice daily to hundredths. Daily discharge ascertained by applying mean daily gage height to rating table. Open-water records good; ice records poor.

COOPERATION.—Base data furnished by United States Engineer Corps.

Discharge measurements of Twelvepole Creek at Wayne, W. Va., during the year ending Sept. 30, 1917.

BIG SANDY RIVER BASIN.

LEVISA FORK AT THELMA, KY.

Location.—At Chesapeake & Ohio Railway bridge at Thelma, Johnston County, 2 miles below Paintsville. Buffalo Creek enters on right about half a mile above station.

Drainage area.—2,090 square miles (measured by United States Engineer Corps).

Records available.—June 1, 1915, to September 30, 1917.

Gage.—Vertical staff gage attached to right shore pier of bridge, portion of gage above 24 feet is cut in masonry steps on upper end of right abutment; read by John Stambaugh. Sea-level elevation of gage, 561.82 feet (United States Engineer Corps).

Discharge measurements.—Made from boardwalk constructed on the lower downstream chord of bridge.

Channel and control.—Channel straight one-half mile above and 300 feet below gage. Bed of stream sandy. Remains of coffer dams around piers, and piles at measuring section. Primary control about 2,400 feet downstream composed of rock which extends three-fourths of the way across stream; remainder is firm sand, fairly permanent.

Extremes of stage.—Maximum, mean gage height during year, 33.85 feet March 5; minimum, mean gage height, 1.50 feet October 14–16. Highest stage recorded, 42.6 feet by present gage.

Ice.—Stage-discharge relation probably not affected by ice.

Regulation.—Splash dams on tributaries and in main stream about 50 miles above used by timber companies may affect low-water flow to some extent.

Accuracy.—Discharge measurements made in 1917 apparently indicate a marked change in stage-discharge relation; additional measurements are needed for confirmation before making a new rating table. Gage read twice daily to hundredths below 10 feet and to tenths above 10 feet. Records good.

Cooperation.—Base data furnished by United States Engineer Corps.

Discharge measurements of Levisa Fork at Thelma, Ky., during the year ending Sept. 30, 1917.

TUG FORK AT KERMIT, W. VA.

Location.—About 150 feet above United Fuel Gas Co.'s ferry at Kermit, Mingo County. Marrowbone Creek enters on right about 2 miles below gage.

Drainage area.—1,240 square miles (measured by United States Engineer Corps).

Records available.—June 1, 1915, to September 30, 1917.

Gage.—Vertical staff gage in three sections attached to trees on right bank of river; 0–20 feet, 160 feet above cable; 20–38 feet, 130 feet below cable; and 38 to 48 feet at cable; read by C. C. Preece. Sea-level elevation of zero of gage, 574.77 feet (United States Engineer Corps).

Discharge measurements.—Made from car on ferry cable or by wading under cable.

Channel and control.—Channel straight above and below, bed of stream sandy; control about 150 feet below cable composed of solid rock which extends half way across from left bank and loose rock placed in river for fording, probably permanent.

Ice.—Stage-discharge relation rarely if ever affected by ice.

Accuracy.—Stage-discharge relation practically permanent; not affected by ice. Rating curve well defined between 85 and 25,000 second-feet; beyond these limits the curve is an extension. Gage read twice daily to hundredths below 10 feet and to tenths above 10 feet. Daily discharge ascertained by applying mean daily gage heights to rating table. Record excellent.

Cooperation.—Base data furnished by United States Engineer Corps.

Discharge measurements of Tug Fork at Kermit, W. Va., during the year ending Sept. 30, 1917.

BLAINE CREEK AT YATESVILLE, KY.

LOCATION.—At covered highway bridge one-fourth mile above Yatesville, Lawrence County. Morgan Branch enters on left about 2 miles above station.

DRAINAGE AREA.—216 square miles (United States Engineer Corps).

RECORDS AVAILABLE.—June 1, 1915, to September 30, 1917.

GAGE.—Vertical staff gage in two sections attached to elm tree on right bank about 50 feet above bridge; read by Hattie M. Carter.

DISCHARGE MEASUREMENTS.—Made from board walk constructed on inside of bridge near top of siding. Wading measurements are made under bridge.

CHANNEL AND CONTROL.—Stream curved above and straight below bridge, right bank overflows at high stages, stream bed compact sand and gravel; control composed of bed rock extending half way across stream, sand and gravel rest of way, probably permanent.

ICE.—Stage-discharge relation rarely affected by ice.

ACCURACY.—Stage-discharge relation probably permanent; not affected by ice. Rating curve well defined between 20 and 4,000 second-feet; extended beyond these limits. Gage read twice daily to hundredths below and tenths above 10 feet. Daily discharge ascertained by applying mean daily gage heights to rating table. Records good.

COOPERATION.—Base data furnished by United States Engineer Corps.

Discharge measurements of Blaine Creek at Yatesville, Ky., during the year ending Sept. 30, 1917.

SCIOTO RIVER BASIN.

SCIOTO RIVER AT WAVERLY, OHIO.

LOCATION.—At Norfolk & Western Railway bridge about 1 mile southeast of Waverly, Pike County.

DRAINAGE AREA.—5,730 square miles (United States Engineer Corps).

RECORDS AVAILABLE.—March 23, 1916 to September 30, 1917.

GAGE.—Chain gage fastened to downstream side of bridge; read by W. G. Johnston. Sea-level elevation of zero of gage, 542.00 feet (United States Engineer Corps).

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge to which gage is attached, or from highway bridge 2,000 feet below gage.

CHANNEL AND CONTROL.—For stages over 12 feet the river spreads over the bottom lands, but all water passes under the bridge.

EXTREMES OF DISCHARGE.—Maximum stage during year, 16.27 feet March 15 (discharge 39,000 second-feet); minimum mean daily discharge, estimated to be about 350 second-feet in September.

ACCURACY.—Stage-discharge relation practically permanent. Rating curve well defined between 400 and 140,000 second-feet. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage heights to rating table, except as noted. Records good.

COOPERATION.—Base data furnished by United States Engineer Corps.

The following discharge measurement was made by Crosley and Baker of the United States Army Engineer Corps:

October 18: Gage height, 1.46, discharge, 437 second-feet.

Daily discharge, in second-feet, of Scioto River at Waverly, Ohio, for the year ending Sept. 30, 1917.

LITTLE MIAMI RIVER BASIN.

LITTLE MIAMI RIVER AT MIAMIVILLE, OHIO.

Location.—At two-span steel highway bridge about one-third mile southeast of Miamiville, Clermont County.

Drainage area.—1,200 square miles.

Records available.—June 21, 1915, to September 30, 1917.

Gage.—Chain gage attached to downstream side of bridge; read by Arnold Barrere.

Discharge measurements.—Made from downstream side of bridge, except at low stages, when they are made by wading.

Channel and control.—Channel clean of vegetation, except at high stages. Control probably permanent.

Extremes of discharge.—Maximum stage recorded during year, 13.5 feet at 4 p. m. January 5 (discharge, 25,600 second-feet); minimum mean daily stage recorded, 1.36 feet, September 25 (discharge, 72 second-feet).

Regulation.—Low-water flow regulated to some extent by operation of flour mill at Fosters Crossing about 11 miles upstream.

Accuracy.—Stage-discharge relation permanent; may be affected by ice to some extent during December 13–25 and January 11–20. Rating curve well defined between 100 and 6,000 second-feet and fairly well above 6,000 second-feet. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Low-stage record subject to error because of artificial regulation.

Cooperation.—Base data furnished by U. S. Army Engineers.

Daily discharge, in second-feet, of Little Miami River at Miamiville, Ohio, for the year ending Sept. 30, 1917.

EAST FORK OF LITTLE MIAMI RIVER AT PERINTOWN, OHIO.

Location.—At single-span steel highway bridge at Perintown, Clermont County, about 5 miles above junction of East Fork and Little Miami rivers.

Drainage area.—459 square miles.

Records available.—May 7, 1915, to September 30, 1917.

Gage.—Chain gage attached to downstream side of bridge; read by G. W. Taylor.

Discharge measurements.—Made from downstream side of bridge except at low stages when they are made by wading.

Channel and control.—Bed of river mostly rock; banks covered with trees and brush above a stage of about 5 feet; control rock and gravel; probably permanent.

Extremes of discharge.—Maximum stage recorded during year, 18.6 feet at noon December 27 (discharge, about 21,300 second-feet); minimum stage, −0.10 foot September 23 (discharge, about 9 second-feet).

Ice.—Stage-discharge relation affected by ice in severe winters.

Accuracy.—Stage-discharge relation permanent; may be affected by ice to some extent during parts of December, January, and February. Rating curve well defined between 10 and 7,000 second-feet. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table.

Cooperation.—Base data furnished by United States Army Engineers.

Discharge measurements of East Fork of Little Miami River at Perintown, Ohio, during the year ending Sept. 30, 1917.

[Made by L. M. Crosley.]

LICKING RIVER BASIN.

LICKING RIVER AT FARMERS, KY.

LOCATION.—About 100 feet below Chesapeake & Ohio Railway bridge and about 300 feet below two-span steel highway bridge, three-fourths of a mile west of Farmers, Rowan County.

DRAINAGE AREA.—768 square miles (measured by United States Engineer Corps).

RECORDS AVAILABLE.—July 20, 1915, to September 30, 1917.

GAGE.—Combination vertical staff and slope gage on east bank of river; read by T. E. Craig.

DISCHARGE MEASUREMENTS.—Made from downstream side of two-span highway bridge 300 feet above gage.

CHANNEL AND CONTROL.—Bed of stream solid rock, straight above and below gage. Control is a rock reef about 1 mile below gage.

EXTREMES OF STAGE.—Maximum stage recorded during year 25.6 feet at 7 a. m. January 22; minimum stage 1.1 feet August 17 and 18.

ICE.—No information.

REGULATION.—The flow at low stages may be affected by storage of water for use of a sawmill at a movable dam a short distance above the gage. Dam is submerged at gage height 5 feet.

ACCURACY.—Stage-discharge relation probably permanent; not affected by ice during the year. On August 4, 1917, the sloping gage was found to be in error as follows: 5-foot mark at elevation 5.04 feet; 4-foot mark at elevation 4.17 feet; and 2-foot mark at elevation 2.23 feet. In the absence of definite information as to date of change in gage, it was assumed that the change occurred March 1, 1916, and remained constant until August 4, 1917, when discovered. Gage readings during this period below 5.0 feet were increased as indicated by the determined errors in the gage. Rating curve not yet determined. Gage read to half-tenths twice daily. Gage readings less than 5 feet are questionable on account of error in gage.

COOPERATION.—Records furnished by United States Engineer Corps.

Daily gage height, in feet, of Licking River at Farmers, Ky., for the year ending Sept. 30, 1917.

NOTE.—No gage height furnished for Sept. 30.

LICKING RIVER AT CATAWBA, KY.

LOCATION.—About 200 feet below Catawba ford, about one-fourth mile north of Catawba, Pendleton County. Kinkaid Creek enters from right about 1,000 feet below gage.

DRAINAGE AREA.—3,300 square miles.

RECORDS AVAILABLE.—July 14, 1916, to September 30, 1917.

GAGE.—Combination slope and vertical staff on south bank of river about 200 feet below the ford; read by G. A. Frank. Elevation of zero of gage is 498.37 feet above sea level, which corresponds approximately to 69 feet on the United States Weather Bureau gage on Ohio River at Cincinnati, Ohio.

DISCHARGE MEASUREMENTS.—Made from cable about 500 feet upstream from gage.

CHANNEL AND CONTROL.—Bed of river at cable is mostly ledge rock. The banks are heavily wooded above an elevation of about 7 feet on the gage. The control is a rock bar just below the mouth of Kinkaid Creek; probably permanent.

EXTREMES OF DISCHARGE.—Maximum stage recorded during period of records, 32.8 feet at 6 a. m. January 23, 1917 (discharge, 55,200 second-feet); minimum stage recorded, 0.80 foot September 28, 1917 (discharge, 89 second-feet).

ICE.—Stage-discharge relation affected by ice during severe winters.

ACCURACY.—Stage-discharge relation probably permanent; not affected by ice during year. Rating curve fairly well defined between 110 and 860 second-feet; and well defined above 860 second-feet; below 110 second-feet the curve is an extension. Gage read twice daily to hundredths. Daily discharge ascertained by applying mean daily gage height to rating table. Records excellent.

COOPERATION.—Base data furnished by United States Army Engineers.

Discharge measurements of Licking River at Catawba, Ky., during the year ending Sept. 30, 1917.

SOUTH FORK OF LICKING RIVER AT HAYES, KY.

Location.—At two-span steel highway bridge at Hayes, Pendleton County, about 2½ miles south of Falmouth.

Drainage area.—922 square miles (measured by United States Engineer Corps).

Records available.—July 7, 1916, to September 30, 1917.

Gage.—Chain gage attached to downstream handrail of bridge; read by J. K. Frazer. Sea-level elevation of zero of gage, 540.10 feet.

Discharge measurements.—Made from upstream side of bridge.

Channel and control.—Bed of river composed of ledge rock; banks lined with vegetation. Control about 800 feet below gage; probably permanent. Backwater begins to affect the stage-discharge relation at this station when the main Licking River reaches a stage of about 28 feet on the gage at Falmouth.

Extremes of stage.—Maximum stage recorded during year, 15.5 feet at 7 a. m. January 22; minimum stage recorded, 0.20 foot at 6 a. m. September 6.

Ice.—Stage-discharge relation not affected by ice except during severe winters.

Accuracy.—Stage-discharge relation probably permanent, except as affected by backwater from the Licking. Not affected by ice during the year. Rating curve not yet determined. Gage read twice daily to hundredths.

Cooperation.—Base data furnished by United States Engineer Corps.

Discharge measurements of South Fork of Licking River at Hayes, Ky., during the year ending Sept. 30, 1917.

MIAMI RIVER BASIN.

MIAMI RIVER AT SIDNEY, OHIO.

Location.—At North Street Bridge, Sidney, Shelby County, Ohio.

Drainage area.—555 square miles.

Records available.—February 1, 1914, to September 30, 1917.

Gage.—Vertical staff attached to downstream side of west abutment; read by H. B. Blake. Elevation of zero of gage, 926.46 feet above mean sea level.

Discharge measurements.—Made from downstream side of the bridge at the gage, from the upstream side of highway bridge about 1,000 feet below the gage, or by wading.

Channel and control.—Shift during floods. Foliage along the banks may cause some backwater at high stages.

Extremes of stage.—The flood of March–April, 1913—the highest known to have occurred at this station—reached a stage March 25 represented by 17.9 feet on gage.

Ice.—Stage-discharge relation may be affected by ice during short periods.

Regulation.—A small power plant a short distance above the gage draws water from the Miami & Erie Canal feeder (see "Diversions"), and discharges it into the river above the gage. Another power plant takes water from Tawawa Creek and discharges it into the river above the point of control, which is just below the gage; this power plant is not in operation during the greater part of the summer for lack of water. The flow is practically unregulated by these power plants.

Diversions.—Water to feed the Miami & Erie Canal is diverted from the river at Port Jefferson, but a part of it is returned to the river above the gage. The amount diverted past the gage may be a large proportion of the low-water flow at the gage. Water diverted is not included in the table of daily discharge.

Accuracy.—Stage-discharge relation practically permanent; not seriously affected by ice during the year. Measurements in 1917 indicate a shift in stage-discharge relation and do not cover sufficient range in stage to define a rating curve. Gage read once daily to tenths.

Cooperation.—Gage-height record furnished by the United States Weather Bureau and results of discharge measurements by the Miami Conservancy District.

MIAMI RIVER AT PIQUA, OHIO.

Location.—At North Main Street Bridge at Piqua, Miami County.

Drainage area.—842 square miles (determined by Morgan Engineering Co.).

Records available.—October 1, 1913, to June 30, 1914; October 1, 1914, to September 30, 1917. The United States Weather Bureau has obtained daily gage readings since January 1, 1911, and flood stages January 1, 1907, to December 31, 1910.

Gage.—Mott gage; read by V. D. Crist. Sea-level elevation of zero of gage, 849 feet.

Discharge measurements.—Made from upstream side of highway bridge about 3,000 feet below gage, or by wading.

Channel and control.—Control shifts somewhat during floods.

Extremes of stage.—Flood of March-April, 1913, highest known at station, reached stage of 23.3 feet March 25, referred to gage datum.

Ice.—Stage-discharge relation affected by ice during winters.

Diversions.—Water from Miami & Erie Canal feeder is taken from the feeder in hydraulic canal and carried through a siphon under Loramie Creek, thence along the edge of the hills to Piqua, where it is used for power. It is discharged into the canal about a mile below the gage. In addition, water is diverted from the river into the lower canal level about 3 miles above the gage. The total diversion is therefore the flow in the "hydraulic" plus the flow in the canal opposite the gage. There has been practically no flow in the canal since the banks were washed out February 1, 1916.

Regulation.—Water is discharged from power plants into the river above the gage, but the effect of the regulation is not appreciable.

ACCURACY.—Stage-discharge relation considered permanent during 1916 and 1917; probably affected by ice during parts of December, January, and February of these two years, although none was reported. Rating curve fairly well defined between 20 and 20,000 second-feet, beyond these limits the curve is an extension. Gage read daily to tenths. Gage-height record previous to October 1, 1914, unreliable. Records October 1, 1915, to September 30, 1917, considered good, except for parts of the winter months when affected by ice.

COOPERATION.—Gage-height record furnished by the United States Weather Bureau. Results of discharge measurements furnished by the Miami Conservancy District.

MIAMI RIVER AT TADMOR, OHIO.

Location.—At National Road bridge at Tadmor, Montgomery County, about 4½ miles below mouth of Honey Creek, which enters from left.

Drainage area.—1,130 square miles (determined by Morgan Engineering Co.).

Records available.—January 1, 1914, to September 30, 1917.

Gage.—Vertical staff in two sections; read by E. J. Shepard. Sea-level elevation of zero of gage, 763.68 feet.

Discharge measurements.—Made from upstream side of bridge at gage or by wading.

CHANNEL AND CONTROL.—May shift slightly during floods.

EXTREMES OF STAGE.—Highest stage known, 25.4 feet, occurred March 25, 1913.

ICE.—Stage-discharge relation may be affected by ice for short periods during severe winters.

DIVERSIONS.—None. All the water diverted into Miami & Erie Canal is wasted into the river several miles above Tadmor.

ACCURACY.—Stage-discharge relation practically permanent; probably affected by ice to some extent during December 14–27, January 14–27, and February 2–19. Rating curve well defined between 99 and 11,000 second-feet and extended beyond these limits. Gage read daily to tenths. Low-water readings are liable to be in error as they do not check closely with hydrographer's readings. Daily discharge ascertained by applying daily gage height to rating table.

The daily discharge as computed by the Miami Conservancy District is published. During rises additional gage readings are made and are used in determining the daily discharge instead of using the regular gage reading alone. In the table of monthly discharge, the maximum daily discharge for many months is the discharge corresponding to a special gage reading and not to the gage reading taken at the regular time. Records good except for periods of very low water or as affected by ice.

COOPERATION.—Gage-height record furnished by the United States Weather Bureau. Results of discharge measurements and daily discharge furnished by the Miami Conservancy District.

a Maximum discharge determined from special reading.
b Minimum discharge determined from special reading.

MIAMI RIVER AT DAYTON, OHIO.

LOCATION.—At Main Street Bridge, Dayton, Montgomery County, about half a mile below mouth of Mad River and 1 mile above mouth of Wolf Creek.

DRAINAGE AREA.—2,520 square miles (determined by Miami conservancy district).

RECORDS AVAILABLE.—March 18, 1905, to December 31, 1909; April 1, 1913, to September 30, 1917.

GAGE.—Vertical staff attached to downstream end of first pier from left bank; read by C. E. Wilson. Sea-level elevation of zero of gage, 723.73 feet.

DISCHARGE MEASUREMENTS.—Made from bridge.

CHANNEL AND CONTROL.—Control apparently shifts considerably at high stages and not so much at low stages. Weeds in the channel sometimes affect stage-discharge relation.

EXTREMES OF STAGE.—The flood of March–April, 1913, reached a stage of 29.0 feet on March 26, as determined by the Miami Conservancy District.

ICE.—Ice may affect the stage-discharge relation during severe winters.

DIVERSIONS.—A power plant about a mile above the station may divert water around the section, and a dam on Mad River about 2 miles above the station diverts water into the Miami & Erie Canal.

ACCURACY.—Stage-discharge relation not permanent; probably affected by ice during the latter part of December and the first part of February. Additional measurements needed in order to define curve for 1917. Gage read daily to tenths.

COOPERATION.—Gage-height record furnished by the United States Weather Bureau. Results of discharge measurements furnished by the Miami Conservancy District.

MIAMI RIVER AT FRANKLIN, OHIO.

Location.—In NW. ¼ sec. 3, T. 1 N., R. 5 E., at suspension bridge on Second Street at Franklin, Warren County. Twin Creek enters about 2¾ miles downstream.

Drainage area.—2,780 square miles (Miami Conservancy District).

Records available.—March 15, 1916 to September 30, 1917.

Gage.—Vertical staff in two sections. Lower section reading 0–12.45 feet bolted to downstream side of old stone abutment on east side of river. Upper section nailed to south side of telephone pole 25 feet below east end of bridge. Read by Mrs. John Coleman. Sea-level elevation of zero of gage 658.41 feet.

Discharge measurements.—Made from downstream side of suspension bridge. Current very sluggish at low stages and low-water measurements are subject to error on that account.

Channel and control.—The principal control consists of a boulder and gravel bar one-half mile below the gage, free from vegetation and apparently permanent.

Extremes of discharge.—Maximum discharge during year, 30,500 second-feet in March; minimum discharge, 460 second-feet in September.

Highest stage known 23.0 feet on March 26, 1913.

Ice.—Stage-discharge relation affected by ice during severe winters.

Regulation.—See "Diversions."

Diversions.—Some water is diverted from the river 2 miles above the gage but it is returned to the river about 800 feet above the station. There is little or no flow in the Miami & Erie Canal at this place.

Accuracy.—Stage-discharge relation practically permanent; probably not affected by ice during the year. Rating curve well defined. Gage read to tenths once daily. Daily discharge ascertained by applying daily-gage height to rating table. Daily discharge as computed by the Miami Conservancy District is published. During rises special gage readings are made which are used in obtaining the mean daily discharge. The maximum monthly discharge in the table of monthly discharge for many months is the discharge corresponding to one of these special readings and does not therefore correspond to the maximum mean daily discharge as given in the table of daily discharge. Records excellent.

Cooperation.—Base data and computed daily discharge furnished by Miami Conservancy District.

a From special gage readings.

MIAMI RIVER AT HAMILTON, OHIO.

LOCATION.—At single-span highway bridge on High Street at Hamilton, Butler County.

DRAINAGE AREA.—3,580 square miles.

RECORDS AVAILABLE.—February 28, 1910, to September 30, 1917. Flood stages only, November 16, 1904, to February 27, 1910, reported by United States Weather Bureau.

GAGE.—Vertical staff attached to a single pile about 75 feet above High-Main Street bridge reading from 0 to 10 feet. A staff fastened to an oak sleeper in the left concrete river wall just above the new bridge reads from 10 feet to 27 feet. Sea-level elevation of zero of gage, 564.63 feet. For description of old gage, see Water-Supply Paper 353.

DISCHARGE MEASUREMENTS.—Made from upstream side of bridge.

CHANNEL AND CONTROL.—Apparently permanent under ordinary conditions. The section at the bridge shifts somewhat during floods on account of the high velocity.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 11.8 feet at 5 p. m. March 13 (discharge, 37,000 second-feet); minimum stage, 1.9 feet September 17-18, 19, 30 (discharge, 370 second-feet).

The maximum stage on record at this station occurred at 3 a. m. March 26, 1913, at gage height 34.6 feet.

According to records of United States Weather Bureau, the highest stage prior to 1913 was 21.2 feet March 24, 1898.

ICE.—Stage-discharge relation affected by ice for short periods during severe weather only, as factory wastes probably keep the temperature of the water above the freezing point.

DIVERSIONS.—The Miami & Erie Canal is fed by water taken from Miami River at Middletown, Ohio. The quantity diverted is about 120 second-feet as shown by discharge measurements made during the summer of 1916.

REGULATION.—There are several power plants in Hamilton above the station, but all the water is returned to the river above the gage.

ACCURACY.—Stage-discharge relation practically permanent; effect of ice is considered negligible. Rating curve fairly well defined between 900 second-feet and 62,000 second-feet. Gage read to tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table except as noted. Records excellent.

COOPERATION.—Results of discharge measurements furnished by Miami Conservancy District.

Discharge measurements of Miami River at Hamilton, Ohio, during the year ending Sept. 30, 1917.

MIAMI RIVER AT VENICE, OHIO.

LOCATION.—About 400 feet downstream from boundary line between Hamilton and Butler counties, at single span highway bridge three-fourths mile southeast of Venice, Butler County. Indian Creek enters from right about 1.4 miles above station.

DRAINAGE AREA.—3,790 square miles (measured by U. S. Army Engineers).

RECORDS AVAILABLE.—June 14, 1915, to September 30, 1917.

GAGE.—Chain gage fastened to downstream side of bridge; read by H. B. Matson.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge.

CHANNEL AND CONTROL.—The control for medium stages is the remains of an old mill dam about 1¼ miles below the gage. For stages below about 3 feet a riffle is formed by an unstable gravel bar under the bridge. This bar scours out during high water and reforms at low stages. All water flows under the bridge for stages less than 25 feet.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 17.7 feet at 7 a. m. March 14 (discharge, 35,600 second-feet); minimum stage, 1.13 feet at 4.30 p. m. November 14 (discharge, about 465 second-feet).

The highest stage known corresponds to about 38 feet on the gage during the 1913 flood.

DIVERSIONS.—The Miami & Erie Canal is fed by water taken from Miami River at Middletown and Miamisburg, Ohio. The canal at Lindenwald near the point where it leaves the drainage basin has a flow of about 100 second-feet which is a considerable part of the low-water flow of Miami River.

REGULATION.—The flow during low stages is probably regulated to a large extent by power plants in Hamilton.

ACCURACY.—Stage-discharge relation practically permanent except for possible slight changes at low stage because of shifts in the gravel bar at the bridge; probably not affected by ice during the year. Rating curve well defined between 460 and 35,000 second-feet. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records good.

COOPERATION.—Base data furnished by the United States Engineer Corps.

The following discharge measurement was made by L. M. Crosley:

November 8, 1917: Gage height, 1.33 feet; discharge, 516 second-feet.

Daily discharge, in second-feet, of Miami River at Venice, Ohio, for the year ending Sept. 30, 1917.

LORAMIE CREEK AT LOCKINGTON, OHIO.

Location.—In NE. ¼ sec. 30, T. 7 N., R. 6 E., at steel highway bridge, half a mile northwest of Lockington, Shelby County, and 1½ miles below mouth of Turtle Creek.

Drainage area.—255 square miles (measured by Miami Conservancy District).

Records available.—September 13, 1915, to September 30, 1917.

Gage.—Vertical staff in two sections; lower section reading 0–10.45 feet, bolted to downstream face of pier; upper section fastened to a tree 100 feet southwest of west end of bridge. Read by Vernon Jones. Sea-level elevation of zero of gage, 875.99 feet.

Discharge measurements.—Made from downstream side of bridge or by wading.

Channel and control.—The principal control is a sand and gravel bar about 100 feet below the gage and is liable to shift. During summer months flow is affected somewhat by a growth of vegetation along the edge of the stream.

EXTREMES OF STAGE.—Highest stage known, 15.6 feet March 25, 1913.

ICE.—The creek is frozen over during severe winters.

DIVERSIONS.—The summit level of the Miami & Erie Canal is supplied by water from the Loramie reservoir. Consequently, water is diverted from Loramie Creek to Lake Erie drainage. There is no flow in the Miami & Erie Canal at Lockington, as the 1913 flood destroyed the canal embankment at a number of places, and no repairs have been made.

REGULATION.—There is a small amount of regulation, due to the storage of water in Loramie reservoir, which controls about 30 per cent of the total drainage area of Loramie Creek.

ACCURACY.—Stage-discharge relation not permanent; not seriously affected by ice during the year. Rating curve not developed. Measurements indicate considerable change in the control. Gage read to tenths once daily. Records good.

COOPERATION.—Base data furnished by Miami Conservancy District.

Discharge measurements of Loramie Creek at Lockington, Ohio, during the year ending Sept. 30, 1917.

STILLWATER RIVER AT PLEASANT HILL, OHIO.

Location.—At steel highway bridge, about three-fourth mile northwest of Pleasant Hill, Miami County, in SE. ¼ sec. 18, T. 7 N., R. 5 E., 4 miles below mouth of Greenville Creek.

Drainage area.—453 square miles (Miami Conservancy District).

Records available.—April 7, 1916, to September 30, 1917.

Gage.—Vertical staff gage in two sections—0 to 10.27 feet bolted to downstream face of pier, 10.27 feet to 20.25 feet bolted to face of downstream wing wall of left abutment. Read by Elmer Herbst.

Discharge measurements.—Made from downstream side of bridge or by wading below the bridge.

Channel and control.—The control is formed of compact rock and gravel about 1,000 feet below the gage; apparently permanent. Channel is straight above and below the bridge. During high floods the water overflows the levee on the left bank and spreads over a wide strip of bottom land.

Extremes of discharge.—Maximum discharge during year, 7,190 second-feet in March; minimum discharge, 10 second-feet in November, December, and January. The highest stage on record, 17.5 feet by present gage, occurred March 25, 1915.

Ice.—Stage-discharge relation occasionally affected by ice.

Accuracy.—Stage-discharge relation probably permanent; may be affected by ice to some extent during portions of December and January. Rating curve well defined from 28 second-feet to 8,800 second-feet; extended beyond these limits. Gage read to tenths daily. Daily discharge ascertained by applying daily gage height to rating table. The daily discharge as computed by Miami Conservancy District is published. During rises special gage readings are made which are used in obtaining the mean daily discharge. The maximum monthly discharge in the table of monthly discharge for many months is the discharge corresponding to one of these special readings and does not, therefore, correspond to the maximum mean daily discharge as listed in the table of mean daily discharge. Records are considered excellent except for periods possibly affected by ice.

Cooperation.—Base data and mean daily discharge are furnished by the Miami Conservancy District.

Discharge measurements of Stillwater River at Pleasant Hill, Ohio, during the years ending Sept. 30, 1916 and 1917.

STILLWATER RIVER NEAR WEST MILTON, OHIO.

Location.—In SE. ¼ sec. 4, T. 4 N., R. 5 E., 1 mile below mouth of Ludlow Creek, entering from right, at bridge of Cleveland, Cincinnati, Chicago & St. Louis Railway (Peoria & Eastern division), about 2 miles north of West Milton, Miami County.

Drainage area.—600 square miles.

Records available.—January 1, 1914, to September 30, 1917.

Gage.—Vertical staff in two sections; read by M. J. Shellhaas. Sea-level elevation of zero of gage, 812.97 feet.

Discharge measurements.—Made from downstream side of railroad bridge at gage, from upstream side of highway bridge about 300 feet below the gage, or by wading.

CHANNEL AND CONTROL.—Regular section shifts slightly during high water; weeds during the summer may affect the stage-discharge relation.

EXTREMES OF STAGE.—Maximum daily stage recorded during year, 8.3 feet in March; mimimum daily stage, 0.5 foot in October.

The flood of March–April, 1913, reached a stage of 28 feet on March 25.

ICE.—Stage-discharge relation affected by ice during severe winters.

ACCURACY.—Stage-discharge relation changes during floods; affected by ice to some extent December 15–26 and January 13–21. Rating curve for 1917 not definitely defined. Gage read daily to tenths. Records good.

COOPERATION.—Gage-height record furnished by United States Weather Bureau. Results of discharge measurements furnished by the Miami Conservancy District.

MAD RIVER NEAR SPRINGFIELD, OHIO.

LOCATION.—At old mill about 800 feet south of Cleveland, Cincinnati, Chicago & St. Louis Railway bridge No. 121 and one-third mile below mouth of Buck Creek, near Springfield, Clark County.

DRAINAGE AREA.—488 square miles.

RECORDS AVAILABLE.—December 31, 1903, to March 31, 1906; February 1, 1914, to September 30, 1917.

GAGE.—Vertical staff in two sections; lower section attached to north wall of rock-lined overflow channel from millrace; upper section attached to south side of old mill building; read by O. W. Bruney. Sea-level elevation of zero of gage, 887.81 feet. The station operated 1903 to 1906 was located about one mile down stream.

DISCHARGE MEASUREMENTS.—Made from highway bridge about 1,000 feet below gage or by wading about 1,500 feet below gage.

CHANNEL AND CONTROL.—Channel shifts slightly during floods.

EXTREMES OF STAGE.—Maximum daily stage recorded during year, 6.8 feet in July; minimum daily stage recorded, 1.1 feet September 26–30.

The flood of March–April, 1913, reached a stage on March 25 represented by 19.2 feet, referred to gage datum.

ICE.—Stage-discharge relation is affected by ice during severe winters.

ACCURACY.—Stage-discharge relation probably permanent, probably not seriously affected by ice during the year. Rating curve for 1917 not definitely defined. Gage read daily to tenths. Records good.

COOPERATION.—Gage-height record furnished by the United States Weather Bureau. Results of discharge measurements furnished by the Miami Conservancy District

MAD RIVER NEAR DAYTON, OHIO.

LOCATION.—In SE. ¼ sec. 8, T. 2 E., R. 8 N. Great Miami base line, at covered highway bridge about a mile northwest of Wright, Greene County, and 5 miles above Dayton.

DRAINAGE AREA.—652 square miles.

RECORDS AVAILABLE.—November 19, 1914, to September 30, 1917.

GAGE.—Vertical staff, attached to the downstream side of west abutment of bridge; read by John Morris. Sea-level elevation of zero of gage, 783.91 feet.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge at gage or by wading about 150 feet above gage.

CHANNEL AND CONTROL.—Stream bed is made up of boulders and gravel; probably permanent.

EXTREMES OF DISCHARGE.—Maximum daily stage recorded during year, 7.4 feet March 14 (discharge, 5,250 second-feet); minimum daily stage, 0.8 foot September 28–30 (discharge, 209 second-feet).

The flood of March–April, 1913, the highest known to have occurred at this station, reached a stage on March 25, represented by 14.0 feet, referred to gage datum.

ICE.—Stage-discharge relation seldom affected by ice, as velocities are high.

ACCURACY.—Stage-discharge relation changed about March 15, 1917; not seriously affected by ice during the years 1915 and 1917. Rating curve used November 19, 1914, to March 14, 1917, failry well defined between 230 and 5,500 second-feet; that used from March 15 to September 30, 1917, well defined between 210 and 6,000 second-feet. Gage read daily to tenths. Daily discharge ascertained by applying daily gage height to rating table. Data for 1915 are republished on account of a revision of the rating curve, and supersede those published in Water-Supply Paper 403. Data as published for 1916 in Water-Supply Paper 433 are correct. Records good.

COOPERATION.—Gage-height record and results of discharge measurements furnished by Miami Conservancy District.

Discharge measurements of Mad River near Dayton, Ohio, during the year ending Sept. 30, 1917.

BUCK CREEK AT SPRINGFIELD, OHIO.

LOCATION.—At Plum Street Bridge in Springfield, Clark County.

DRAINAGE AREA.—163 square miles.

RECORDS AVAILABLE.—July 15, 1914, to September 30, 1917.

GAGE.—Vertical staff in two sections; read by S. Van Bird, jr. Elevation of zero of gage above sea level, 908.2 feet.

DISCHARGE MEASUREMENTS.—Made from upstream side of bridge or by wading.

CHANNEL AND CONTROL.—Channel may shift slightly during floods.

EXTREMES OF STAGE.—Maximum daily stage recorded during year, 5.9 feet, January 5; minimum daily stage, 0.5 foot, September 27.

The flood of March-April, 1913, the highest known to have occurred at this station, reached a stage on March 25, represented by 12.3 feet, referred to gage datum.

ICE.—Stage-discharge relation affected by ice for short periods only, as the use of water for condensing purposes at points above the gage tends to keep the temperature above freezing.

ACCURACY.—Stage-discharge relation not permanent; probably not affected by ice. Rating curve for 1917 not definitely defined. Gage read daily to tenths. Records good.

COOPERATION.—Base data furnished by the Miami Conservancy District.

Discharge measurements of Buck Creek at Springfield, Ohio, during the year ending Sept. 30, 1917.

TWIN CREEK NEAR GERMANTOWN, OHIO.

Location.—At covered highway bridge in NE. ¼ sec. 14, T. 3 N., R. 4 E., about 1 mile west of Germantown, Montgomery County, and about 2 miles above mouth of Little Twin Creek, which enters from left.

Drainage area.—272 square miles.

Records available.—April 12, 1914, to September 30, 1917.

Gage.—Vertical staff in two sections; read by Thomas Stettler. Sea-level elevation of zero of gage, 712.73 feet.

Discharge measurements.—Made from downstream side of the bridge or by wading about 200 feet above gage. The bridge makes an angle of about 45° with the direction of the current. Flood measurements can be made at the highway bridge about half a mile below the gage.

Channel and control.—Channel shifts slightly during floods.

Extremes of stage.—Maximum daily stage recorded during year, 7.1 feet, March 14; minimum daily stage, 0.8 foot, September 18-30. The flood of March–April, 1913, the highest known to have occurred at this station, reached a stage on March 25 of 18.3 feet, referred to gage datum.

Ice.—Stage-discharge relation affected by ice during severe winters.

ACCURACY.—Stage-discharge relation not permanent; probably not affected by ice. Rating curve not developed. Measurements indicate considerable change in control. Gage read daily to tenths. Records good.

COOPERATION.—Station maintained and records furnished by the Miami Conservancy District.

Discharge measurements of Twin Creek near Germantown, Ohio, during the year ending Sept. 30, 1917.

FOURMILE CREEK NEAR SEVENMILE, OHIO.

LOCATION.—In NW. ¼ sec. 7, T. 2 N., R. 3 E. first principal meridian, at steel-truss highway bridge about 2 miles southwest of Sevenmile, Butler County, and about 5 miles above junction with Miami River, near Hamilton.

DRAINAGE AREA.—178 square miles.

RECORDS AVAILABLE.—November 17, 1914, to September 30, 1917.

GAGE.—Vertical staff in two sections; read by W. B. Eaton. The lower section is on downstream side of bridge pier; upper section is on tree on right bank just below bridge. Sea-level elevation of zero of gage, 618.69 feet.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge at gage or by wading 700 feet above gage.

CHANNEL AND CONTROL.—Stream bed is composed of gravel; shifts considerably during floods.

EXTREMES OF STAGE.—Maximum daily stage recorded during year, 6.5 feet June 5; minimum daily stage, 0.5 foot October 11–15, 17. Maximum stage recorded, 18 feet, March 25, 1913.

ICE.—Stage-discharge relation may be affected by ice jams at times.

ACCURACY.—Stage-discharge relation not permanent; probably not seriously affected by ice during the year. Rating curve not developed. Recent measurements indicate some change in control. Gage read to tenths daily. Records good.

COOPERATION.—Gage-height recorded and results of discharge measurements furnished by the Miami Conservancy District.

Discharge measurements of Fourmile Creek near Sevenmile, Ohio., during the year ending Sept. 30, 1917.

SEVENMILE CREEK AT SEVENMILE, OHIO.

LOCATION.—On line between sec. 5, T. 2 N., R. 3 E., and sec. 32, T. 3 N., R. 3 E. first principal meridian, at covered highway bridge about half a mile west of Sevenmile, Butler County, and about 1 mile above junction with Fourmile Creek.

DRAINAGE AREA.—128 square miles.

RECORDS AVAILABLE.—November 17, 1914, to September 30, 1917.

GAGE.—Vertical staff on downstream side of west abutment; read by H. L. Kumler. Sea-level elevation of zero of gage, 623.1 feet.

DISCHARGE MEASUREMENTS.—Made from bridge at gage or by wading just above bridge.

CHANNEL AND CONTROL.—Stream bed at the gage is for the most part limestone bedrock in horizontal layers; although some gravel occurs along the east side, the section is practically permanent.

EXTREMES OF STAGE.—Maximum daily stage recorded during year, 7.8 feet January 5; minimum daily stage, 1.4 feet August 19–20. Maximum stage recorded, 17 feet, March 25, 1913.

ICE.—Stream is seldom covered with ice on account of the high velocities, but stage-discharge relation is sometimes affected by ice jams.

ACCURACY.—Stage-discharge relation practically permanent; not seriously affected by ice during the year. Rating curve not developed. Gage read daily to tenths. Records good.

COOPERATION.—Gage-height record and results of discharge measurements furnished by the Miami Conservancy District.

Discharge measurements of Sevenmile Creek at Sevenmile, Ohio, during the year ending Sept. 30, 1917.

NOTE.—No readings Mar. 4–17.

WHITEWATER RIVER AT BROOKVILLE, IND.

LOCATION.—At two-span steel highway bridge about three-fourths mile south of Brookville, Franklin County, and about 2,000 feet below junction of east and west forks of Whitewater River.

DRAINAGE AREA.—1,180 square miles.

RECORDS AVAILABLE.—June 8, 1915, to September 30, 1917.

GAGE.—Chain gage fastened to downstream side of bridge; read by H. Koerner.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge.

CHANNEL AND CONTROL.—Control about 500 feet below gage is probably permanent.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 13.7 feet March 13 (discharge, about 39,000 second-feet); minimum stage, 1.05 feet morning February 14 (discharge, 164 second-feet).

REGULATION.—Flow regulated to some extent by the Thompson-Norris strawboard mill at Brookville. Water is diverted from the west fork about 10 miles above station and flows down the old Whitewater Canal to the mill and is returned to the river a few hundred feet above junction of the east and west forks.

ACCURACY.—Stage-discharge relation practically permanent; probably not affected by ice during year. Rating curve well-defined between 200 and 12,500 second-feet; beyond these limits curve is an extension. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage heights to rating table. Records good.

COOPERATION.—Base data furnished by United States Army Engineers.

Daily discharge, in second-feet, of Whitewater River at Brookville, Ind., for the year ending Sept. 30, 1917.

KENTUCKY RIVER BASIN.

DIX RIVER NEAR BURGIN, KY.

LOCATION.—At covered wooden highway bridge on Burgin and Buena Vista pike, 3¾ miles due east of Burgin, Mercer County. Kennedy's mill is one-fourth mile above station.

DRAINAGE AREA.—395 square miles (86 per cent measured on topographic maps and 14 per cent on map of Kentucky, compiled by United States Geological Survey, scale 1:500,000).

RECORDS AVAILABLE.—July 2, 1910, to July 16, 1911; October 1, 1911, to September 30, 1917.

GAGE.—Staff gage attached to right upstream wing wall of bridge near face of abutment; read twice daily by Frank Martin. Soundings taken at the measuring section indicate that the zero of the gage as replaced by the observer on February 15, 1913, is approximately 0.2 foot below zero of gage installed when station was established. Gage readings subsequent to February 15, 1913, refer to a datum which is about 0.2 foot below datum of original gage.

DISCHARGE MEASUREMENTS.—Made from upstream side of bridge, from a boat, or by wading.

CHANNEL AND CONTROL.—Probably permanent except during extreme floods. At stages above low water the growth of foliage on trees and brush at the control may affect the stage-discharge relation to a small extent.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 29.0 feet about 3 a. m. January 22 (discharge, 27,500 second-feet); minimum stage, 2.80 feet July 11–14 (discharge, 2.5 second-feet).

Maximum stage about 30 feet; date unknown.

ICE.—Ice forms only during severe winters.

ACCURACY.—Stage-discharge relation practically permanent; not affected by ice during the year. Rating curve well defined up to 455 second-feet and fairly well defined between 455 and 12,000 second-feet; extended above 12,000 second-feet. Gage read twice daily to quarter tenths. Daily discharge ascertained by applying mean daily gage height to rating table. Records good.

COOPERATION.—Station maintained in cooperation with Kentucky State Geological Survey, J. B. Hoeing, State geologist.

Discharge measurements of Dix River near Burgin, Ky., during the year ending Sept. 30, 1917.

[Made by Jones and Sellier.]

ELKHORN CREEK AT FORKS OF ELKHORN, KY.

LOCATION.—At footbridge at Forks of Elkhorn, Franklin County, three-fourths mile below forks of stream and 5 miles northeast of Frankfort.

DRAINAGE AREA.—415 square miles (measured by United States Engineer Corps).

RECORDS AVAILABLE.—April 26, 1915, to September 30, 1917.

GAGE.—Vertical staff in two sections on left bank; section reading 0 to 5 feet attached to elm tree 40 feet below bridge, other section attached to sycamore tree about 20 feet below bridge; read by R. S. Estes.

DISCHARGE MEASUREMENTS.—Made from footbridge.

CHANNEL AND CONTROL.—Bed of stream loose and bed rock; probably permanent. Control short distance below gage, composed of solid rock and boulders; permanent.

ICE.—Stage-discharge relation probably not affected by ice except during severe winters.

ACCURACY.—Stage-discharge relation probably permanent; not affected by ice during year. Rating curve well defined, 65 to 18,000 second-feet and fairly well defined at other stages. Gage read twice daily to tenths. Daily discharge ascertained by applying mean gage readings to rating table. Results good.

COOPERATION.—Base data furnished by United States Engineer Corps.

EAGLE CREEK AT GLENCOE, KY.

LOCATION.—At county highway bridge half a mile south of Glencoe, Gallatin County,

DRAINAGE AREA.—445 square miles (United States Engineer Corps).

RECORDS AVAILABLE.—April 29, 1915, to September 30, 1917.

GAGE.—Vertical staff attached to upstream side of first pier from left abutment of bridge; read by Anna Connelly.

DISCHARGE MEASUREMENTS.—Made from bridge.

CHANNEL AND CONTROL.—Bed of stream sand and loose stone; probably permanent. Small island covered with trees about 250 feet below bridge. Point of control not determined.

ICE.—Stage-discharge relation probably not affected by ice except in very cold winters.

ACCURACY.—Stage-discharge relation probably permanent; not affected by ice during year. Rating curve well defined between 50 and 15,000 second-feet, extended beyond these limits. Gage read twice daily to tenths. Daily discharge ascertained by applying mean daily gage height to rating table. Records good.

COOPERATION.—Base data furnished by United States Engineer Corps.

The following discharge measurement was made by C. J. Thiebaud, of the United States Army Engineer office at Frankfort, Ky.:

May 12, 1917: Gage height, 1.40 feet; discharge, 83.1 second-feet.

Daily discharge, in second-feet, of Eagle Creek at Glencoe, Ky., for the year ending Sept. 30, 1917.

GREEN RIVER BASIN.

GREEN RIVER AT MUNFORDVILLE, KY.

LOCATION.—At toll highway bridge at Munfordville, Hart County. Louisville & Nashville Railroad bridge is about a mile below highway bridge.

DRAINAGE AREA.—1,790 square miles (measure on map of Kentucky compiled by United States Geological Survey, scale 1: 500,000.)

RECORDS AVAILABLE.—February 27, 1915, to September 30, 1917.

GAGE.—Chain gage attached to upstream handrail of bridge; read by Chester Williams.

DISCHARGE MEASURMENTS.—Made from upstream side of bridge or by wading 100 feet below the bridge.

CHANNEL AND CONTROL.—The control for low stages is at a riffle used as a ford immediately below the bridge and is believed to be permanent; control at high stages is also believed to be permanent. Discharge relation may be affected to some extent at high stages by differences in the foliage on the brush and trees in the flood plain.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 35.5 feet at 5.30 a. m. January 7 (discharge, 31,400 second-feet); minimum stage, 2.85 feet at 5.30 a. m. July 7 (discharge, 128 seond-feet). Minimum discharge for 1916 was 118 second feet and not 144, as given in this paragraph in Water-Supply Paper 433.

Highest known stage, about 54 feet; date unknown.

ICE.—Ice seldom forms at this station.

ACCURACY.—Stage-discharge relation practically permanent; not affected by ice during the year. Rating curve well defined below and fairly well defined above 1,700 second-feet. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Record good.

COOPERATION.—Station maintained in cooperation with the Kentucky Geological Survey, J. B. Hoeing, State geologist.

Discharge measurements of Green River at Munfordville, Ky., during the year ending Sept. 30, 1917.

[Made by B. E. Jones.]

WABASH RIVER BASIN.

VERMILION RIVER NEAR DANVILLE, ILL.

Location.—In sec. 22, T. 19 N., R. 11 W., at Chicago & Eastern Illinois Railroad bridge, about 3 miles south of Danville, Vermilion County, 1¼ miles above Stony Creek, and 3 miles below mouth of North Fork.

Drainage area.—1,280 square miles.

Records available.—November 12, 1914, to September 30, 1917.

Gage.—Chain gage attached to downstream side of bridge; read by Ralph Bradbury till July 14 and by William Taylor afterward.

Discharge measurements.—Made from downstream side of bridge or by wading.

Channel and control.—Soft mud and sand; likely to shift.

Extremes of discharge.—Maximum stage recorded during year, 13.4 feet at 4.30 a. m. June 6 (discharge, 7,840 second-feet); minimum stage, 2.20 feet at 6.30 a. m. October 3 (discharge, 16 second-feet).

1915–1917: Maximum stage recorded, 18.9 feet January 31, 1916 (discharge, 12,800 second-feet); minimum stage, 2.00 feet November 20 and 23 to 25, 1915 (discharge, 15 second-feet).

Accuracy.—Stage-discharge relation not permanent; affected by ice and changed during high water in June. Rating curve used till June 5 fairly well defined between 35 and 10,000 second-feet; curve used after that date fairly well defined between 52 and 10,000 second-feet. Gage read to hundredths twice daily. Gage heights probably 1.0 foot in error for a period just before or after July 8. Daily discharge ascertained by applying mean daily gage height to rating tables. Records fair except for very low stages in October and November, for period affected by ice, and for period about July 8, for which they are poor.

Discharge measurements of Vermilion River near Danville, Ill., during the year ending Sept. 30, 1917.

[Made by H. C. Beckman.]

NOTE.—No gage height record for Mar. 2 and Sept. 23–24; discharge interpolated. Discharge estimated July 2–8 because of erroneous gage heights. Discharge Dec. 11 to Feb. 28 estimated because of ice, from gage heights, observer's notes, and weather records. Braced figures show mean discharge for periods included.

Monthly discharge of Vermilion River near Danville, Ill., for the year ending Sept. 30, 1917.

EMBARRASS RIVER AT STE. MARIE, ILL.

Location.—In sec. 30, T. 6 N., R. 14 W., at highway bridge at north end of Main Street, Ste. Marie, Jasper County, about 450 feet downstream from Cincinnati, Indianapolis & Western Railway bridge, and 2½ miles upstream from mouth of Hickory (or North Fork) Creek.

Drainage area.—1,540 square miles.

Records available.—October 20, 1909, to December 31, 1912; August 24, 1914, to September 30, 1917.

Gage.—Standard chain gage attached to bridge; read by V. C. Wuerth.

Discharge measurements.—Made from downstream side of highway bridge at ordinary stages; during high water made also from downstream side of five wooden trestles on Cincinnati, Indianapolis & Western Railway bridge, northwest of highway bridge.

Channel and control.—Measuring section is at a pool; control is about 1,800 feet below gage; may shift.

Extremes of discharge.—Maximum stage recorded during year, 21.2 feet at 8 a. m. June 6 (discharge, 14,000 second-feet); minimum stage recorded, 1.51 feet at 3 p. m. November 8 (discharge, 22 second-feet).

Flood of spring of 1908 reached a height of 22.5 feet on the present gage (discharge not determined). Minimum stage during periods of records, 1.1 feet September 5 to 9, 1914, and October 19, 1914 (discharge, 1.0 second-foot).

Accuracy.—Stage-discharge relation probably permanent throughout the year; seriously affected by ice during the winter. Rating curve fairly-well defined between 35 and 5,030 second-feet; above 5,030 second-feet it is based on an extension of curve for main river channel and estimated overflow. Gage read to hundredths once daily. Daily discharge ascertained by applying daily gage heights to rating table. Records fair, except for extremely low stages, for highest stages in June and for periods of ice effect.

Discharge measurements of Embarrass River at Ste. Marie, Ill., during the year ending Sept. 30, 1917.

WEST BRANCH OF WHITE RIVER NEAR NOBLESVILLE, IND.

Location.—In sec. 16, T. 19 N., R. 5 E. At steel highway bridge known as Conners Bridge, about 4½ miles north of Noblesville, Hamilton County.

Drainage area.—900 square miles (measured on 1,500,000 scale map).

Records available.—May 13, 1915, to September 30, 1917.

Gage.—Chain gage attached to upstream side of bridge; read by Marvin Scearce.

Discharge measurements.—Made from downstream side of bridge or by wading.

Channel and control.—Coarse sand and gravel, strewn with boulders; probably permanent.

Extremes of stage.—Maximum stage recorded during year, 10.1 feet at 4.35 p. m. March 14; minimum stage, 1.26 feet 4.10 p. m. October 12.

Ice.—Stage-discharge relation affected by ice during severe winters.

Accuracy.—Stage-discharge relation probably permanent; probably affected by ice last part of December, middle of January and first half of February. Rating curve not determined. Gage read twice daily to hundredths. Station last visited on October 21, 1916.

Cooperation.—Gage-height record furnished by Noblesville Heat, Light & Power Co., Noblesville, Ind.

No measurements made at this station by engineers of Survey during the year.

Daily gage height, in feet, of West Branch of White River near Noblesville, Ind., for the year ending Sept. 30, 1917.

LITTLE WABASH RIVER AT WILCOX, ILL.

Location.—In SW. ¼ sec. 3, T. 2 N., R. 8 E., at highway bridge at Wilcox, Clay County, about 6 miles southeast of Clay City and a quarter of a mile below mouth of Big Muddy Creek.

Drainage area.—1,130 square miles.

Records available.—August 22, 1914, to September 30, 1917.

Gage.—Standard chain gage attached to bridge; read by Hugh Holman.

Discharge measurements.—At ordinary stages made from downstream side of bridge, which is at a pool; during high water made also from bridge across drainage ditch and overflow section about half a mile east of the highway bridge.

Channel and control.—Heavy clay, probably permanent; control section is about 100 feet below the bridge. A determination by soundings August 22, 1914, indicates that there would be no flow past the gage if the stage were to fall to about 1.2 feet.

Extremes of discharge.—Maximum stage recorded during year 22.2 feet at 5 a. m. June 8 (discharge, 6,290 second-feet); minimum stage, 1.88 feet October 12 and 13 (discharge, 6.6 second-feet).

1914–1917: Maximum stage prevailed August 22, 1915 (gage inaccessible, discharge estimated as 10,000 second-feet); minimum stage recorded, 1.70 feet August 23, 1914 (discharge, 4 second-feet).

Accuracy.—Stage-discharge relation practically permanent; affected by ice during most of winter. Rating curve well defined between 63 and 420 second-feet, fairly well defined below 63 second-feet and between 420 and 3,360 second-feet, and poorly defined above 3,360 second-feet. Gage read to hundredths once daily. Daily discharge ascertained by applying daily gage height to rating table. Records good except for very high stages and for periods affected by ice, for which they are poor.

Discharge measurements of Little Wabash River at Wilcox, Ill., during the year ending Sept. 30, 1917.

NOTE.—No gage height record for Nov. 13, 17, and 21, and Sept. 20 and 21; discharge interpolated. Discharge Dec. 11–31 and Jan. 11 to Feb. 20 estimated, because of ice, from gage heights, observer's notes, and weather records. Braced figures show mean discharge for periods included.

Monthly discharge of Little Wabash River at Wilcox, Ill., for the year ending Sept. 30, 1917.

[Drainage area, 1,130 square miles.]

SKILLET FORK AT WAYNE CITY, ILL.

Location.—In sec. 18, T. 2 S., R. 6 E., at Southern Railway bridge 1 mile east of Wayne City, Wayne County, and about 4 miles below mouth of Horse Creek.

Drainage area.—481 square miles.

Records available.—August 16, 1908, to December 31, 1912; June 22, 1914, to September 30, 1917.

Gage.—Standard chain gage attached to bridge; read by J. C. Taylor.

Discharge measurements.—Made from downstream side of bridge; in high water also from downstream side of wooden trestle about 1 mile east of main channel. Low-water measurements made by wading below gage.

Channel and control.—Channel practically permanent; rough. Control is remains of rock dam at bridge section. A determination by leveling on August 20, 1914, indicated that there would be no flow past the gage if the stage fell to 1.6 feet.

Extremes of discharge.—Maximum stage recorded during year, 21.3 feet at 8 a. m. January 6 (discharge, 8,600 second-feet); minimum stage, 2.00 feet October 10 to 14 and September 25 to 30 (discharge, 0.8 second-foot).

Maximum stage recorded during periods of records, 23.1 feet August 22, 1915 (discharge, 15,800 second-feet); zero flow existed for 54 days in September to December, inclusive, of 1908.

Diversions.—About 30,000 gallons of water per day are pumped from river above gage into service tank of Southern Railway.

Accuracy.—Stage-discharge relation permanent; affected by ice during periods in winter. Rating curve fairly well defined between 15 and 5,000 second-feet, and poorly defined beyond these limits. Gage read to hundredths once daily. Daily discharge determined by applying daily gage height to rating table. Record good for medium stages; poor for very high stages and periods affected by ice. Determinations greater than 6,000 second-feet subject to considerable error because of poor definition and flatness of rating curve.

Discharge measurements of Skillet Fork at Wayne City, Ill., during the year ending Sept. 30, 1917.

NOTE.—On the following days the water was over the top of the gage and the gage height was estimated by comparison with the U. S. Weather Bureau readings at Burnside; determinations for single days are subject to considerable error, but the effect on the monthly mean would not be great: 1908, Feb. 11-12, 15-17, Mar. 2-4, 19-20, Apr. 2-4, 26-27; 1909, Jan. 16-18, Feb. 11, 17-18, 24-26, Mar. 9-11, 25-27, Apr. 21-22, May 2, July 14, Aug. 17; 1910, Jan. 8, Feb. 18-19; 1911, Jan. 2-5, Feb. 8-9, Mar. 7-10, Apr. 5-7, 16, May 1-2.

Monthly discharge of Cumberland River at Cumberland Falls, Ky., for years ending Sept. 30, 1907-1912, and 1917.

[Drainage area, 2,040 square miles.]

CUMBERLAND RIVER AT BURNSIDE, KY.

Location.—Below mouth of South Fork of Cumberland River, at Burnside, Pulaski County.

Drainage area.—4,890 square miles (measured on maps of Kentucky and Tennessee. prepared by United States Geological Survey on scale 1 : 500,000).

Records available.—October 1, 1914, to September 30, 1917.

Gage.—Vertical staff in two sections on piers of toll bridge across South Fork of Cumberland River about 700 feet above mouth; installed in July, 1914, by United States Weather Bureau. Readings on this gage by the Weather Bureau began January 1, 1915. Sea-level elevation of zero, 589.53 feet (Smith Shoals Survey datum, United States Engineer Corps), this datum being same as that of gage which was marked on the rails of inclines 1 and 2 leading from the South Fork to the warehouse, about 500 feet below the present gage, and which was established in 1884 and read daily until January 1, 1915. Upper part of old gage, reading from 54 to 71 feet, was spiked to office of Col. Cole. The United States Weather Bureau[1] reports that "the old river gage was changed on several unknown dates and by amounts that are uncertain, so that readings prior to January 1, 1915, are not comparable by from 0.1 to 0.7 foot." New gage is read for the United States Geological Survey by L. M. Cheeley.

Discharge measurements.—Flow of South Fork is measured from the highway bridge; the Cumberland above the South Fork is measured from a boat from the Queen & Crescent Railroad bridge, or by means of floats, the method used depending on the stage: flow below the South Fork is the combined flow of both streams.

Channel and control.—Channel considered permanent except for deposits of mud, which are washed away at high stages. Low-water control is crest of dam No. 21, 28 miles below Burnside; gage height of crest of dam, 1.47 feet. The dam is a recently built concrete structure, and probably little or no water leaks through dam or lock.

Extremes of discharge.—Maximum stage recorded during year, 51.4 feet at 4 p. m. January 5 (discharge, roughly, 115,000 second-feet); minimum, 1.97 feet, July 13 and 14, due to lowering of pool to flood steamer off bar below lock.

Maximum stage recorded, 62 feet March 31, 1886; minimum, —1.6 feet November 8 and 9, 1895; at present lowest stage possible is 1.47 feet, unless pool No. 21 is lowered.

Ice.—Stage-discharge relation seldom affected by ice.

Regulation.—Stage at low water will be affected by any manipulation of the level of pool No. 21 at the lock.

Accuracy.—Stage-discharge relation practically permanent; not materially affected by ice during 1915, 1916, and 1917. Rating curve fairly well defined to 30,000 second-feet (gage height approximately, 20 feet); curves extend above 30,000 second-feet and may be considerably in error. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height or daily gage height to rating table. Gage readings October 1, 1914, to February 18, 1915, obtained from gage readings at Lock No. 21, and the Weather Bureau's old and new gages. At low-water stage discharge relation may be affected by water entering between the gage and the dam due to heavy local showers in the basins of the small intervening tributaries. Results are good for discharge less than 30,000 second-feet.

Cooperation.—Station maintained in cooperation with the Kentucky Geological Survey, J. B. Hoeing, State geologist.

SOUTH FORK OF CUMBERLAND RIVER AT NEVELSVILLE, KY.

Location.—One-fourth mile below Turkey Creek ferry, on Greenwood-Monticello pike about a mile from Nevelsville, McCreary County. Little South Fork enters on left about 1¾ miles above station.

Drainage area.—1,260 square miles (measured on maps of Kentucky and Tennessee, compiled by United States Geological Survey, on scale 1:500,000).

Records available.—March 10, 1915, to September 30, 1917.

Gage.—Vertical staff gage in 5 sections bolted to rock ledges on left bank; read by Mart Keith and Ben Whitehead. A reference gage for use in referencing soundings at the measuring section, is attached to a tree on the left bank 110 feet below cable.

Discharge measurements.—Made from cable about 2,000 feet below gage, or by wading.

CHANNEL AND CONTROL.—Channel straight above and below; bed, compact gravel. Low-water control is partly the bed of the river below gage and partly a gravel bar about 2 miles below gage. Both are probably permanent. High-water control is bed of stream for several miles below gage, and may be slightly affected by foliage along the banks.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 35.1 feet, at 5.30 p. m., March 3 (discharge, roughly, 55,000 second-feet; minimum stage, 1.82 feet, at 5.30 a. m., July 13 (discharge, 64 second-feet).

ICE.—Stage-discharge relation seldom if ever affected by ice.

REGULATION.—Operation of a small power plant short distance above gage may affect flow at extreme low water.

ACCURACY.—Stage-discharge relation probably permanent; not affected by ice during period of record. Rating curve well defined to 23,000 second-feet. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records excellent.

COOPERATION.—Station maintained in cooperation with State Geological Survey of Kentucky, J. B. Hoeing, State geologist.

Discharge measurements of South Fork of Cumberland River at Nevelsville, Ky., during the year ending Sept. 30, 1917.

[Made by B. E. Jones.]

CANEY FORK NEAR ROCK ISLAND, TENN.

Location.—About 100 feet downstream from power house of Tennessee Power Co., half a mile downstream from mouth of Collins River, and 1 mile northwest of Rock Island, Warren County.

Drainage area.—1,640 square miles (measured on Post Route Map).

Records available.—November 14, 1911, to September 30, 1917.

Gage.—Bristol water-stage recorder, known as gage No. 3, 100 feet downstream from power house and about half a mile downstream from Rock Island dam; this gage has been used to determine the mean daily stage since January 1, 1917. From March 26 to December 31, 1916, a Bristol water-stage recorder installed March 26, 1916, at site of staff gage known as gage B (No. 2), half a mile upstream from gage No. 3 and 300 feet downstream from Rock Island dam, was used for determining mean daily stages. The closing of sluice gates in dam on December 8, 1916, and diversion of flow through tunnel on December 12 made gage B useless after December 7, 1916. Prior to March 26, 1916, daily mean stage was determined from a water-stage recorder known by the Billesby Co., as gage A, 400 feet upstream from gage B, just above point at which dam is now built; date of installation of recorder not known. Backwater from dam began to affect stage-discharge relation at gage A March 26, 1916.

Discharge measurements.—Formerly made from cable at gage B or from sluiceways in dam. No discharge measurements have been made since closing of the sluiceways December 8, 1916.

Channel and control.—Bed of stream above and below gage consists chiefly of solid rock; probably permanent.

Extremes of discharge.—Maximum discharge during year, about 55,000 second-feet (estimated by comparison with flow of Collins River); March 4, stage unknown; minimum stage, 0.35 foot November 20 (discharge, 330 second-feet).

1911–1917: Maximum stage recorded, 13.2 feet April 2, 1912 (discharge, 107,000 second-feet); minimum stage 0.20 foot September 17, 20, 21, and October 4, 5, 10, 1914 (discharge, 220 second-feet).

Regulation.—Prior to December 8 only slight diurnal fluctuation caused by operation of small mills upstream. After that date considerable regulation resulted from storage in reservoir above.

Accuracy.—Stage-discharge relation practically permanent. Rating curve used prior to December 8 well defined between 300 and 25,000 second-feet, and extended above. Above 4,700 second-feet and below 430 second-feet curve is based on rating curve constructed by the H. M. Billesby Engineering Co., Chicago, Ill. Rating curve used subsequent to January 1 developed by means of simultaneous gage readings at gage B (No. 2) and gage No. 3, and based upon the above curve, is fairly well defined between 300 and 9,000 second-feet and extended above. Mean daily gage heights computed by Tennessee Power Co. Daily discharge ascertained by applying mean daily gage height to rating table. Records good except for extreme high stages.

Cooperation.—Gage-height record furnished by Tennessee Power Co.

The following discharge measurement was made by L. J. Hall:

November 10, 1916: Gage height (gage No. 2 B), 0.41 foot; discharge, 367 second-feet.

Daily discharge, in second-feet, of Caney Fork near Rock Island, Tenn., for the year ending Sept. 30, 1917.

31	470	....	....	12,600	....	6,940	....	1,490	....	1,490	700	....

NOTE.—Records Oct. 1 to Dec. 7 obtained from gage B (No. 2) at site immediately below dam, which represents normal flow. Dec. 8 to 31 the flow past gage B was regulated by closing of sluice gates in dam. Diversion of water through tunnel at power house, about half a mile below gage B, was begun Dec. 12. Records for this period omitted. Discharge Mar. 3 and 4 estimated by comparison with records of flow of Collins River.

Records Jan. 1 to Sept. 30, obtained from gage No. 3 at site 100 feet below power house and about half a mile below gage B, represent total flow, which is however, subject to considerable regulation from dam above.

Monthly discharge of Caney Fork near Rock Island, Tenn., for the year ending Sept. 30, 1917.

[Drainage area, 1,640 square miles.]

COLLINS RIVER NEAR ROWLAND, TENN.

LOCATION.—At Hennessee's iron highway bridge, 1 mile below Mountain Creek, 2½ miles northeast of Rowland, Warren County, 5 miles southwest of Rock Island, and about 8 miles upstream, by river, from junction of Collins River with Caney Fork, a tributary of Cumberland River.

DRAINAGE AREA.—800 square miles (measured by Tennessee Power Co.).

RECORDS AVAILABLE.—April 1, 1916, to September 30, 1917.

GAGE.—Standard chain gage on downstream side of bridge at middle of second span from right bank; read by Joe Keathley. Zero of gage, 795.86 feet, above sea level.

DISCHARGE MEASUREMENTS.—Made from upstream handrail of bridge, or at extremely low stages, by wading. A stay wire about 100 feet upstream is used to make high-water measurements.

CHANNEL AND CONTROL.—Bed composed of rock, boulders and sand. Channel fairly straight for a considerable distance above and below gage; right bank is a steep rock bluff; left bank is low and subject to overflow above a stage of 8 feet. A series of rock and boulder riffles beginning just below bridge forms the control; probably permanent.

EXTREMES OF DISCHARGE.—1916–17: Maximum stage recorded, 14.1 feet at 12 m. March 4, 1917 (discharge, 28,900 second-feet); minimum stage, 1.10 feet several days in November, 1916 (discharge, 120 second-feet).

By means of levels the elevation of marks of the flood of 1854 (exact date unknown), reported by old residents nearby, indicates that the river rose to stage 32.6 feet (discharge estimated at 82,200 second-feet). Elevation of marks of the flood of 1902 (exact date unknown), obtained in the same manner, indicates a stage of 27.2 feet (estimated discharge, 66,600 second-feet).

ICE.—Stage-discharge relation not affected by ice.

REGULATION.—Small mills upstream probably cause some diurnal fluctuation.

ACCURACY.—Stage-discharge relation practically permanent; not affected by ice. Rating curve well defined below 8,000 second-feet and extended above that point. Gage read to hundredths twice daily; oftener during high water. Daily discharge ascertained by applying mean daily gage height to rating table. Records good. Determination of discharge above stage of overflow (about 8 feet, discharge, 11,300 second-feet) subject to error.

COOPERATION.—Gage-height record furnished by Tennessee Power Co.

Discharge measurements of Collins River near Rowland, Tenn., during the years ending Sept. 30, 1916 and 1917.

TENNESSEE RIVER BASIN.

FRENCH BROAD RIVER AT ASHEVILLE, N. C.

Location.—At new concrete highway bridge which replaced old Smith's bridge; washed out July 16, 1916, about a mile below Southern Railway station at Ashe, ville, N. C., and 2 miles below mouth of Swannanoa River.

Drainage area.—987 square miles.

Records available.—March 19, 1903 (determinations of daily discharge from Jan. 1, 1905) to July 16, 1916; January 1 to September 30, 1917. A record was obtained at Bingham School bridge about three miles west of Ashville from 1895 to 1905.

Gages.—A temporary vertical staff a short distance above the old Smith's bridge was used January 1 to September 30, 1917. Original gages, a vertical staff attached to one of the piers of the old Smith's bridge, and an auxiliary chain gage (for obtaining readings below zero) attached to that bridge, were used until the flood in July, 1916. Readings from the temporary gage have been reduced to the datum of the original gage.

Discharge measurements.—Formerly made from downstream side of highway bridge.

Channel and control.—Bed composed chiefly of rock; practically permanent. Control formed by rock shoal and concrete piers of Southern Railway bridge; permanent, though piers of bridge may become choked with débris during extreme floods, so that stage-discharge relation at gage may be affected by backwater for short periods.

Extremes of discharge.—Maximum stage recorded during year, 4.2 feet March 5 and 25 (discharge, 9,770 second-feet); minimum stage recorded during year, −0.7 foot August 30 (discharge, 680 second-feet).

1905–1917: Maximum stage recorded, 24.13 feet July 16, 1916, determined from flood marks by levels November 21, 1917 (discharge not determined); stage-discharge relation probably affected by backwater from drift lodged against the Southern Railway bridge. Maximum stage recorded before or after the flood in July, 1916, 7.8 feet January 23, 1906 (discharge, 25,800 second-feet). Minimum recorded, −0.7 foot September 16 and 20, 1907 (discharge, 380 second feet.)

ICE.—Stage-discharge relation not affected by ice.

REGULATION.—Slight diurnal fluctuations may be caused by the operation of small mills upstream.

ACCURACY.—Stage-discharge relation changed slightly by the flood in July, 1916. Rating curve based on four discharge measurements made in 1918; well defined below 10,800 second-feet. Gage read to tenths once daily. Daily discharge determined by applying daily gage height to rating table. Records fair.

COOPERATION.—Gage-height record furnished by United States Weather Bureau.

No discharge measurements were made at this station during the year.

Daily discharge, in second-feet, of French Broad River at Asheville, N. C., for the year ending Sept. 30, 1917.

TENNESSEE RIVER AT CHATTANOOGA, TENN.

LOCATION.—At Walnut Street Bridge in Chattanooga, Hamilton County, 3 miles above mouth of Chattanooga Creek, 4 miles below mouth of Chickamauga Creek, and 33 miles upstream from Hales Bar dam.

DRAINAGE AREA.—21,400 square miles (measured on topographic maps).

RECORDS AVAILABLE.—April 1, 1873, to October 21, 1913; March 1, 1915, to September 30, 1917.

GAGES.—Two gages, 7 miles apart and set to the same datum, are used at this station to determine variation in slope of water surface caused by operation of power plant and locks at Hales Bar dam, as the station is within influence of backwater from the dam. Gage No. 1 consists of a sloping section of a railroad T rail, bolted to rock, and a vertical section of timber attached to the rock cliff on the left bank about 200 feet upstream from the Walnut Street Bridge; read by O. B. Gladish and L. M. Andress. Gage No. 2 is a vertical staff in three sections, fastened to trees on left bank about 100 feet above the Cincinnati Southern Railroad bridge 7 miles upstream from Chattanooga; gage is read by C. A. Brown.

Prior to October 21, 1913, gage No. 1 was used alone, but on that date backwater from Hales Bar dam began to affect the stage-discharge relation, and the station was abandoned until March 1, 1915, when gage No. 2 was installed.

DISCHARGE MEASUREMENTS.—Made from downstream footway of Walnut Street Bridge.

CHANNEL AND CONTROL.—Channel practically permanent. Control now formed by Hales Bar lock and dam and power plant.

EXTREMES OF DISCHARGE.—Maximum stage during year, from records of United States Weather Bureau, 47.7 feet at 8.40 a. m. March 7, (discharge, 313,000 second-feet); minimum mean daily discharge, 11,000 second-feet, October 8.

1874–1917: Maximum stage recorded, 64.0 feet at 7 a. m. March 1, 1875 (discharge 361,000 second-feet); minimum stage recorded, zero on gage September 11–14, 1881, and September 19, 1883 (discharge, 4,800 second-feet).

ICE.—Stage-discharge relation not affected by ice.

REGULATIONS.—See "Accuracy."

ACCURACY.—Stage-discharge relation affected by changes in slope of water surface caused by operation of power plant at Hales Bar dam and by rising and falling stages. Discharge determined by slope method (see Water-Supply Paper 345). Rating curve well defined between 11,500 and 363,000 second-feet. Gages read to hundredths twice daily. Records fair.

Discharge measurements of Tennessee River at Chattanooga, Tenn., during the year ending Sept. 30, 1917.

[Made by L. J. Hall.]

TENNESSEE RIVER AT FLORENCE, ALA.

Location.—At Southern Railway bridge at lower end of Pattons Island, just below foot of Little Muscle Shoals, 1 mile south of Florence, Lauderdale County.

Drainage area.—30,800 square miles.

Records available.—November 7, 1871, to September 30, 1917.

Gage.—Rod gage consisting of four sections of steel, three-eighths inch by 7½ inches, attached to right face of stone draw pier, which has batter of 1 inch to the foot. These sections form one continuous gage, graduated from −1.92 to 33.5 feet. Zero of gage, 400.85 feet above sea level. Gage read by R. E. Coburn. For description of gages used prior to September 30, 1913, see Water-Supply Paper 353, p. 151.

Discharge measurements.—Made from downstream side of highway section (the low-level or through section) of 17-span combined railway and highway bridge. Special care necessary to counteract effect of obstruction of current by piers.

Channel and control.—Bed rocky, rough, and uneven; probably permanent. Control practically permanent.

Extremes of discharge.—Maximum stage recorded during year, 24.7 feet at 6 p. m., March 12 (discharge, 319,000 second-feet); minimum stage, 0.1 foot at 7 a. m. and 6 p. m., September 26, and 7 a. m., September 27 (discharge, 12,100 second-feet).

1871–1917: Maximum stage recorded, 32.5 feet at 10 and 12 p. m., March 19, 1897 (discharge, 499,000 second-feet); minimum stage, −0.80 foot September 18, 1878 (discharge, 7,350 second-feet).

Ice.—Stage-discharge relation not affected by ice.

Regulation.—The operation of Hales Bar lock and dam, 175 miles upstream, may cause some diurnal fluctuation in low-stage flow.

Accuracy.—Stage-discharge relation practically permanent. Rating curve well defined above 12,000 second-feet. Gage read to tenths twice daily; oftener during high water. Daily discharge ascertained by applying mean daily gage height to rating table. Records good.

Cooperation.—Gage-height record furnished by Mississippi River Commission.

Discharge measurements of Tennessee River at Florence, Ala., during the year ending Sept. 30, 1917.

TENNESSEE RIVER AT JOHNSONVILLE, TENN.[1]

LOCATION.—At Nashville, Chattanooga & St. Louis Railway freight elevator, about 1,000 feet below railway bridge at Johnsonville, Humphreys County, 96 miles from mouth of Tennessee River and 160 miles below Florence, Ala.

DRAINAGE AREA.—38,500 square miles.

RECORDS AVAILABLE.—October 1, 1875, to September 30, 1917. Records from October 1, 1875, to September 30, 1913, published in Water-Supply Paper 353.

[1] For detailed history of this station see Water-Supply Paper 353, pp. 195-201.

GAGE.—Staff at freight elevator on right bank, about 1,000 feet below the Nashville, Chattanooga & St. Louis Railway bridge.

DISCHARGE MEASUREMENTS.—Made from downstream and upstream side of through railway bridge of six spans and draw span.

CHANNEL AND CONTROL.—No information concerning control. Channel at measuring section at bridge composed of boulders and coarse gravel; apparently permanent.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 38.9 feet March 18, caused partly by backwater from the Ohio River; minimum stage, 1.3 feet November 16–20 (discharge, 13,400 second-feet).

The highest unquestioned record of stage is 48 feet March 24, 1897.

ICE.—Stage-discharge relation not materially affected by ice.

ACCURACY.—Stage-discharge relation is considered permanent except for effect of backwater from Ohio River. No discharge measurements made at this station since August 1, 1914. Not affected by ice during the year. Rating curve well defined between discharges 9,370 and 302,000 second-feet. Gage read once daily to tenths. Daily discharge ascertained by applying daily gage heights to rating table except for period when flow was affected by backwater from Ohio River (see footnote to table of daily discharge). Records good except those estimated which are fair.

COOPERATION.—Gage-height record furnished by United States Weather Bureau.

No discharge measurements were made at this station during the year.

Daily discharge, in second-feet, of Tennessee River at Johnsonville, Tenn., for the year ending Sept. 30, 1917.

SOUTH FORK OF HOLSTON RIVER AT BLUFF CITY, TENN.

Location.—At highway bridge at Bluff City, Sullivan County, 300 feet below Virginia & Southwestern Railway bridge, 1 mile below mouth of Indian Creek, and about 10 miles upstream from mouth of Watauga River.

Drainage area.—828 square miles.

Records available.—July 17, 1900, to September 30, 1917.

Gage.—Vertical staff attached to downstream side of bridge pier, nearest the right bank.

Discharge measurements.—Made from downstream side of bridge; also from railroad bridge 300 feet above where the section is much better except at low stages when the current becomes sluggish.

Channel and control.—Bed of river very rough. Control consists of a shallow ledge; probably permanent. Depth and velocity of current very irregular.

Extremes of discharge.—Maximum stage recorded during year, 9.3 feet at noon, March 5 (discharge, 15,600 second-feet); minimum stage recorded zero, August 28 and 29 (discharge, 185 second-feet).

1900–1917: Maximum stage recorded, 11.45 feet February 28, 1902 (discharge, 33,000 second-feet); minimum stage recorded, −0.1 foot October 16–19, 21–25, 26, 28–31, and November 1, 1904 (discharge, 150 second-feet).

Ice.—Stage-discharge relation not affected by ice.

Regulation.—Some diurnal fluctuation caused by operation of small mills upstream.

Accuracy.—Stage-discharge relation practically permanent. Rating curve fairly well defined below 25,700 second-feet. Gage read to tenths once daily. Daily discharge ascertained by applying daily gage height to rating table. Records good, except those for stages below 800 second-feet, which are only fair, owing to lack of discharge measurements for checking the rating curve at low water.

Cooperation.—Gage-height record furnished by United States Weather Bureau.

Daily discharge, in second-feet, of South Fork of Holston River at Bluff City, Tenn., for the year ending Sept. 30, 1917.

HOLSTON RIVER NEAR ROGERSVILLE, TENN.

LOCATION.—At Virginia & Southwestern Railway bridge near Austin Mill, Hawkins County, half a mile below new county highway bridge, 2 miles downstream from mouth of Dodson Creek, 3 miles south of Rogersville, and 11 miles northeast of Bulls Gap, Tenn.

DRAINAGE AREA.—3,060 square miles.

RECORDS AVAILABLE.—March 10, 1902 (daily discharge record beginning January 1, 1904) to September 30, 1917.

GAGE.—Vertical staff attached to right side of bridge pier nearest the right bank.

DISCHARGE MEASUREMENTS.—Made from the steel highway bridge, about half a mile upstream from gage.

CHANNEL AND CONTROL.—Bed of stream composed of solid rock, boulders and gravel. Right bank high and not subject to overflow; left bank high, but subject to overflow at extremely high stages. Control formed by rock shoals below bridge; practically permanent.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 17.1 feet at 8 a. m. March 5 (discharge, 56,300 second-feet); minimum stage recorded, 1.4 feet at 8 a. m., November 9, 10, December 18, and September 17–27 (discharge, 850 second-feet).

1904–1917: Maximum stage recorded, 19.1 feet, March 28, 1913 (discharge, about 67,000 second-feet); minimum stage recorded, 1.0 foot October 23 to November 3, 1904 (discharge, 490 second-feet).

ICE.—Stage-discharge relation not affected by ice.

REGULATION.—Operation of power plants a long distance upstream causes some diurnal fluctuations in stage.

ACCURACY.—Stage-discharge relation practically permanent; not affected by ice. Rating curve well defined below 33,000 second-feet; extended above that point. Gage read to tenths once daily. Daily discharge ascertained by applying daily gage height to rating table. Records fair.

Discharge measurements of Holston River near Rogersville, Tenn., during the year ending Sept. 30, 1917.

[Made by L. J. Hall.]

LITTLE TENNESSEE RIVER AT JUDSON, N. C.

LOCATION.—At footbridge near Southern Railway Station at Judson, Swain County.

DRAINAGE AREA.—668 square miles (measured by Knoxville Power Co. on topographic maps).

RECORDS AVAILABLE.—April 16, 1912, to September 30, 1915; January 1, 1916, to September 30, 1917; June 25, 1896, to September 30, 1913, at old station of Geological Survey at Southern Railway bridge.

GAGE.—Friez water-stage recorder about 500 feet below footbridge.

CHANNEL AND CONTROL.—Practically permanent.

EXTREMES OF DISCHARGE.—Maximum mean daily discharge during year, 23,000 second-feet, March 4; minimum mean daily stage, 17.53 feet, August 29 (discharge, 602 second-feet).

1892–1912: Maximum stage recorded (old Geological Survey station) 13.92 feet, December 29, 1901 (discharge, 57,500 second-feet); minimum stage recorded 2.10 feet, October 13 to November 1 and December 20, 1904 (discharge, 275 second-feet).

1913–1917: Maximum mean daily discharge (Knoxville Power Co.'s station), 23,000 second-feet March 4, 1917; minimum mean daily stage recorded, 17.1 feet, September 17, October 1 and 2, 1914 (discharge, 380 second-feet).

ICE.—Stage-discharge relation not affected by ice.

COOPERATION.—Daily discharge record furnished by Knoxville Power Co.

Daily discharge, in second-feet, of Little Tennessee River at Judson, N. C., for the years ending Sept. 30, 1916 and 1917.

NOTE.—Monthly discharge computed by engineers of the Geological Survey from daily discharge record furnished by the Knoxville Power Co.

TUCKASEGEE RIVER AT BRYSON, N. C.

Location.—At highway bridge in Bryson, Swain County, half a mile below mouth of Deep Creek and about 15 miles above junction of Tuckasegee River with Little Tennessee River.

Drainage area.—673 square miles (measured by Knoxville Power Co. on topographic maps).

Records available.—November 7, 1897, to September 30, 1915; January 1, 1916, to September 30, 1917.

Gage.—Friez water-stage recorder, installed February 3, 1914 by the Knoxville Power Co., about 200 feet below the bridge to which old staff gage of the Geological Survey was attached. The old staff gage was used prior to installation of Friez gage.

Discharge measurements.—Made from downstream side of bridge.

Channel and control.—Bed probably changes slightly after each flood, but conditions quickly become normal. Control composed of boulders; practically permanent.

Extremes of discharge.—Maximum mean daily stage recorded during year, 10.7 feet March 4 (discharge, 23,200 second-feet); minimum mean daily stage, 1.22 feet November 8 and 9 (discharge, 616 second-feet).

1898–1917: Maximum stage recorded, 11.0 feet (old Geological Survey gage) March 19, 1899 (discharge, 38,600 second-feet); minimum discharge recorded, 300 second-feet several days in September, October, and November, 1899, and August 25, 1902.

Ice.—Stage-discharge relation not affected by ice.

Cooperation.—Daily-discharge record furnished by the Knoxville Power Co.

Daily discharge, in second-feet, of Tuckasegee River at Bryson, N. C., for the years ending Sept. 30, 1916 and 1917.

NOTE.—Monthly discharge computed by engineers of U. S. Geol. Survey from daily-discharge records furnished by Knoxville Power Co.

HIWASSEE RIVER AT MURPHY, N. C.

LOCATION.—At highway bridge 100 feet upstream from Louisville & Nashville Railroad bridge, 300 feet from railroad station, which is on right side of river, four blocks from Murphy post office, Cherokee County, and half a mile upstream from mouth of Valley River.

DRAINAGE AREA.—410 square miles.

RECORDS AVAILABLE.—June 26, 1896, to August 8, 1897; October 19, 1897, to June 30, 1917.

GAGE.—Chain gage attached to downstream side of bridge; read by Miss Willie Mingus.

DISCHARGE MEASUREMENTS.—Made from upstream side of bridge.

CHANNEL AND CONTROL.—At gage the bed is mostly solid rock, and river is confined by masonry bridge abutments. Below gage the bed of stream is composed largely of sand and gravel. Low-water control is formed by a gravel and boulder riffle; high-water control is formed partly by masonry piers of railroad bridge and the riffles below. Control is changeable, owing to shifting of material that forms upper riffle.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 14.7 feet at noon, March 4 (discharge, 19,700 second-feet); minimum stage recorded, 5.2 feet at 7 a. m. October 13-18, 28 and 29 (discharge, 375 second-feet).

1896-1917: Maximum stage recorded, 18.4 feet March 19, 1899 (discharge, 22,400 second-feet); minimum stage recorded, 4.8 feet September 18, 1914 (discharge, 140 second-feet).

ICE.—Stage-discharge relation not affected by ice.

REGULATION.—Negligible.

ACCURACY.—Stage-discharge relation practically permanent during year. Rating curve fairly well defined below 3,700 second-feet. Gage read to half-tenths once daily. Daily discharge ascertained by applying daily gage height to rating table. Records fair.

Discharge measurements of Hiwassee River at Murphy, N. C., during the year ending Sept. 30, 1917.

[Made by L. J. Hall.]

VALLEY RIVER AT TOMOTLA, N. C.

LOCATION.—At steel highway bridge 600 feet from Tomotla post office, Cherokee County, on Southern Railway, 5 miles northeast of Murphy, N. C.; half a mile upstream from Rodgers Creek, and 1 mile downstream from Colvards Creek.

DRAINAGE AREA.—120 square miles.

RECORDS AVAILABLE.—June 29, 1904, to December 31, 1909; January 21, 1914, to April 30, 1917, when station was discontinued temporarily.

GAGE.—In two sections; lower section, 0.0 to 5.4 feet, is on a sloping timber which is bolted to marble bedrock; upper section, 5.4 to 10 feet, is a vertical staff bolted to timber on old bridge pier. This is the same gage that was in use when station was discontinued in 1909. Gage read by J. T. Hayes.

DISCHARGE MEASUREMENTS.—Made from new single-span steel bridge over site of old footbridge.

CHANNEL AND CONTROL.—Bed of channel composed of gravel, which shifts during big floods. Control, which was at first thought to be a permanent rock ledge just below bridge, now seems to be partly formed by gravel bars in conjunction with the ledge; shifts during great floods.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 15.9 feet at noon, March 4 (discharge, 10,100 second-feet); minimum stage recorded, 1 foot at 6 p. m. October 13, and 7 a. m. and 6 p. m., October 14–16 (discharge, 60 second-feet).

1904–1909 and 1914–1917: Maximum stage recorded, 17.3 feet November 19, 1906 (discharge, about 10,400 second-feet); minimum stage recorded, 0.7 foot October 28 to November 2, 1904 (discharge, 22 second-feet).

ICE.—Stage-discharge relation not affected by ice.

REGULATION.—Very little diurnal fluctuation caused by operation of small mills upstream.

ACCURACY.—Stage-discharge relation probably permanent during year. Rating curve fairly well defined between 60 and 400 second-feet; extension of curve above 400 second-feet not considered accurate. Gage read to tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records fair for stages below 500 second-feet.

Discharge measurements of Valley River at Tomotla, N. C., during the year ending Sept. 30, 1917.

NOTTELY RIVER NEAR RANGER, N. C.

LOCATION.—About half a mile downstream from Ranger, Cherokee County, which is on Louisville & Nashville Railroad, 7½ miles from Murphy, N. C., and 8 miles upstream from Hiwassee River, to which Nottely River is tributary.

DRAINAGE AREA.—272 square miles.

RECORDS AVAILABLE.—February 16, 1901, to December 31, 1905; January 22, 1914, to April 30, 1917, when station was discontinued temporarily.

GAGE.—Rod gage fastened to a large birch tree on left bank 75 feet upstream from highway bridge; zero same as for original gage which was destroyed by fire in 1913, when a new steel bridge replaced old wooden one. Gage read by A. D. Kilpatrick.

DISCHARGE MEASUREMENTS.—Made from downstream side of steel highway bridge on road from Ranger to Murphy, N. C. Measuring section is poor and uneven and current somewhat erratic, necessitating very careful measurements.

CHANNEL AND CONTROL.—Bed composed of boulders, gravel, and sand; permanent. Right bank high; left bank subject to overflow beyond bridge end at stages above 18 feet. Control is formed by a low shoal about 300 feet downstream from gage: permanent.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 17.4 feet (estimated by observer) at 7 a. m. March 1 (discharge, about 5,780 second-feet); minimum stage recorded, 3.0 feet October 4–18, 23–31, and November 19–22 (discharge, 265 second-feet).

1901–1905 and 1914–1917: Maximum stage recorded, 19.4 feet at 10 a. m. July 10, 1916 (discharge, 6,580 second-feet); minimum stage recorded, 2.1 feet July 2 and 3, August 9, September 9–11, 14–16, 29 and 30, and October 1–4, 1914 (discharge, 89 second-feet).

ICE.—Stage-discharge relation not affected by ice.

REGULATION.—The operation of small mills upstream may cause slight diurnal fluctuations, but not enough to affect accuracy of determinations.

ACCURACY.—Stage-discharge relation permanent; not affected by ice. Rating curve well defined below but extended above 800 second-feet. Gage read to tenths twice daily; gage not extended for use above stage 10 feet; determinations of flood stages subject to error, as they are obtained by measuring from reference point. Daily discharge ascertained by applying mean daily gage height to rating table. Records for stages below 800 second-feet, fair; for those above, poor.

Discharge measurements of Nottely River near Ranger, N. C., during the year ending Sept. 30, 1917.

TOCCOA RIVER NEAR DIAL, GA.

Location.—About 2,600 feet above Shallow Ford, 1 mile above Stanley Creek, 2½ miles below Big Creek, 3½ miles below Noontootley Creek, about 4 miles northwest of Dial, Fannin County, and about 12 miles by river above gaging station at Morganton.

Drainage area.—175 square miles (measured on topographic maps).

Records available.—January 1, 1913, to September 30, 1917. Records were obtained at Butts Bridge about 2 miles above Dial May 17, 1907, to June 30, 1908.

Gage.—Bristol water-stage recorder. Sea-level elevation of zero of auxiliary staff gage, 1,781.13 feet.

Discharge measurements.—Made from cable about 1,000 feet upstream from gage.

Channel and control.—Bed of stream consists of gravel and boulders; fairly smooth. Left bank is overflowed at a stage of about 12 feet. Control is formed by the head of rapids just below gage; probably permanent.

Extremes of discharge.—Maximum mean daily stage during year, 6.47 feet March 4 (discharge, 4,700 second-feet); minimum stage, daily mean, 1 foot September 19 and 20 (discharge, 195 second-feet).

1913–1917: Maximum stage recorded, 10 feet at 6 p. m. July 9, 1916 (discharge 9,200 second-feet); minimum stage, 0.55 foot October 13, 29, and 30, 1914 (discharge, 109 second-feet).

Regulation.—There are slight diurnal fluctuations due to operation of small mills upstream.

Accuracy.—Stage-discharge relation practically permanent. Rating curve well defined below 4,000 second-feet; extended above 4,000 second-feet. Stage-discharge relation never affected by ice. Daily discharge ascertained by applying to the rating table mean daily gage height determined by inspecting gage-height graph. Records excellent.

Discharge measurements of Toccoa River near Dial, Ga., during the year ending Sept. 30, 1917.

[Made by L. J. Hall.]

TOCCOA RIVER NEAR MORGANTON, GA.

Location.—At highway bridge on road from Blueridge, Ga., to Morganton, half a mile downstream from mouth of Star Creek, 2 miles west of Morganton post office, Fannin County, 4 miles east of Blueridge, 12 miles downstream from Dial gaging station, 14 miles upstream from Georgia-Tennessee State line at Copperhill, Tenn., and 28 miles upstream from gaging station on Ocoee River at Emf, Tenn. At State line name of river is changed from Toccoa to Ocoee.

Drainage area.—231 square miles (measured on topographic maps).

Records available.—November 25, 1898, to March 31, 1903, and April 1, 1913, to September 30, 1917. Records 1898 to 1903 published in Water-Supply Paper 197, under "Toccoa River near Blueridge, Ga.

Gage.—Bristol water-stage recorder on right bank 200 feet downstream from bridge and 150 feet downstream from the old vertical staff which was used from 1898 to 1903. Zeros of both gages, 1,544.5 feet above sea level, but on account of the slope in water surface the readings of the two gages do not agree for all stages. The water-stage recorder was installed in 1914 (exact date not recorded). A rod gage has been placed at site of automatic gage. Observer visits gage every day and checks record sheet with rod reading.

Discharge measurements.—Made from cable about 1,800 feet downstream from gage.

Channel and control.—Bed composed of gravel and bowlders. Banks high; left subject to overflow at about gage height 15 feet; right bank not subject to overflow. Low-water control is a low shoal or riffle just below gage; high-water control is combination of shoals and banks. Control subject to small shifts at low stages.

Extremes of discharge.—Maximum mean daily stage during year, 10.2 feet March 4 (discharge, 9,410 second-feet); minimum stage, mean from water-stage recorder, 2.50 feet October 15 (discharge, 285 second-feet).

1913–1917: Maximum stage recorded, 13.0 feet at 9 p. m. July 9, 1916 (discharge, 13,900 second-feet); minimum stage, 1.8 feet September 10, 14–17, 29, 30, and October 1, 1914 (discharge, 129 second-feet).

Regulation.—Slight diurnal fluctuations probably caused by operation of small mills upstream.

Accuracy.—Stage-discharge relation for stages below 870 second-feet changed during highwater March 4, 1917. Rating curve used to March 4 well defined below 3,500 second-feet and an extension above that point; curve used subsequent to March 4 is well defined below 3,500 second-feet and coincides with previous curve above 870 second-feet; change below 870 second-feet due to slight shift in low-water control. Stage-discharge relation not affected by ice. Daily discharge ascertained by applying to the rating table mean daily gage height obtained by inspecting gage-height graph. Records good.

Discharge measurements of Toccoa River near Morganton, Ga., during the year ending Sept. 30, 1917.

OCOEE RIVER AT McHARGE, TENN.

Location.—At Rogers Ferry county highway bridge, Polk County, about half a mile downstream from McHarge railroad siding, half a mile downstream from mouth of Potato Creek, and 2½ miles downstream from Copperhill, Tenn.

Drainage area.—451 square miles (measured on topographic maps).

Records available.—May 1, 1917, to September 30, 1917.

Gage.—Vertical staff bolted to left downstream side of concrete bridge pier on left bank; read by B. V. Karaivanoff.

CHANNEL AND CONTROL.—Left bank subject to overflow at extreme stages, but water will always pass under bridge. Channel straight for about 300 feet above and 700 feet below gage. Control consists of solid rock riffle about 300 feet below gage; practically permanent.

EXTREMES OF DISCHARGE.—Maximum stage recorded during period of records, 6.0 feet, at 4 p. m., August 30 (discharge not determined); minimum stage recorded, 0.7 foot at 4 p. m., September 14 and 7 a. m., Septenber 15 (discharge, 445 second-feet).

ICE.—Stage-discharge relation not affected by ice.

REGULATION.—None.

ACCURACY.—Stage-discharge relation permanent; not affected by ice. Rating curve well defined between 400 and 2,000 second-feet; extended above 2,500 second-feet. Gage read to half-tenths twice daily; oftener during high water. Daily discharge ascertained by applying mean daily gage height to rating table. Records good.

Discharge measurements of Ocoee River at McHarge, Tenn., during the year ending Sept. 30, 1917.

OCOEE RIVER AT EMF, TENN.

Location.—About 600 feet below Tennessee Power Co.'s plant No. 2, known as the "Caney Creek plant," half a mile upstream from Emf post office, Polk County, 1½ miles downstream from mouth of Goforth Creek, and 8 miles upstream from Parksville, Tenn.

Drainage area.—530 square miles (determined by Tennessee Power Co.).

Records available.—January 1, 1913, to September 30, 1917.

Gage.—Bristol water-stage recorder on left bank; checked daily with a staff gage which is bolted to rock near the Bristol. Readings from gage give elevation above sea-level.

Discharge measurements.—Made from cable at first good section one-half mile downstream from gage, near Emf post office.

Channel and control.—Bed of stream for several hundred feet below gage is composed of boulders, gravel and solid rock. Banks high, subject to small overflow. Control is formed by a shoal and island 700 feet downstream from gage; probably permanent.

Extremes of discharge.—Maximum mean daily stage during year, 12.7 feet March 4 (discharge, 19,200 second-feet); minimum stage, mean for day, from water-stage recorder, 3.15 feet on October 8 (discharge, 440 second-feet).

1913, 1917: Maximum stage recorded, 13.7 feet at 12.30 a. m. July 10, 1916 (discharge, 21,400 second-feet); minimum stage, 2.77 feet September 15–17, 1914 (discharge, 285 second-feet).

Regulation.—The operation of plant No. 2 causes considerable fluctuation at times, but, as a rule, this plant runs on a steady load, the quantity of water used depending largely on stage of river. Storage at diversion dam very small. When plant is shut down water overflows dam in a short time, so that periods of fluctuation will be short.

Accuracy.—Stage-discharge relation practically permanent; not affected by ice. Rating curve well defined between 400 and 8,000 second-feet; above 8,000 second-feet curve is extended as a tangent. Daily discharge ascertained by applying to rating table mean daily gage height determined by inspecting gage-height graph. Records excellent.

Discharge measurements of Ocoee River at Emf, Tenn., during the year ending Sept. 30, 1917.

[Made by L. J. Hall.]

Date.	Gage height.	Discharge.	Date.	Gage height.	Discharge.
	Feet.	*Sec.-ft.*		*Feet.*	*Sec.-ft.*
Oct. 12	3.26	594	Aug. 29	3.26	513
Feb. 20	7.22	7,110	Sept. 16	3.36	592
Aug. 23	3.39	676			

Note.—Discharge measurements, Aug. 29, and Sept. 16, were made from the suspension bridge 1,200 feet downstream from gage; measuring section good. All measurements at this station prior to Aug. 29, 1917, were made from the cable, 2,000 feet downstream from gage; measuring section rough. Discharge measurements made at the new section indicate that measurements at the old section gave too high results for stages below 2,000 second-feet.

Daily discharge, in second-feet, of Ocoee River at Emf, Tenn., for the year ending Sept. 30, 1917.

BIG BEAR RIVER NEAR RED BAY, ALA.

Location.—At Norman Bridge 2½ miles east of Red Bay, Franklin County, 3 miles east of Mississippi State line, 4 miles downstream from mouth of Blue Creek, and 35 miles upstream from junction with Tennessee River.

Drainage area.—254 square miles (measured on map compiled by United States Geological Survey, 1912; scale, 1:500,000).

Records available.—August 24, 1913, to September 30, 1917.

GAGE.—Vertical staff attached to a sweet-gum tree on left bank, 25 feet upstream from bridge; read by Ed Bullen. On February 27, 1917, gage was found to have settled 0.27 foot. Gage was correct on January 2, 1915, when it was checked with bench mark. Flood of July, 1916, is assumed to have undermined tree to which gage is attached, causing it to settle. On April 9 and 11, 1918, settlement of gage was found to have increased to 0.53 foot at gage height 1.5 feet, the error increasing to 0.66 foot at 8.0-foot mark on gage, owing to inclination of gage. A gradual settlement of gage from July, 1916, to April 9, 1918, has been assumed and corrections applied to observer's gage readings before determining discharge.

CHANNEL AND CONTROL.—Bed of river consists of gravel; probably shifting. During extreme low water current is sluggish and irregular. Left bank subject to overflow at stages above 12 feet. Control is a gravel bar 100 feet downstream; practically permanent except for a shift which probably occurred in April, 1917.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 13.9 feet April 6 (discharge, 4,760 second-feet): minimum discharge, 20 second-feet September 13, 15, and 26.

1913–1917: Maximum stage recorded, 14.2 feet at 7 p. m. July 9, 1916 (discharge, 5,720 second-feet); minimum discharge, 15 second-feet July 7, 8, and September 18, 1914.

ICE.—Stage-discharge relation not affected by ice.

ACCURACY.—Stage-discharge relation practically permanent from 1913 until the high water in April, 1916, when the shift in control indicated by current-meter measurements made in April, 1918, probably occurred. Rating curve used August 24, 1913, to April 5, 1917, well defined between 400 and 3,000 second-feet and fairly well defined outside these limits. Curve used April 6 to September 30, 1917, well defined between 80 and 4,000 second-feet; poorly defined below 80 second-feet. Gage read to tenths once daily. Daily discharge ascertained by applying daily gage height to rating table. Records good from August, 1913, to probably June, 1916. Records from July to December, 1916, are only fair, and at low stages may be considerably in error, owing to large percentage errors introduced by small errors in gage-height corrections noted in paragraph concerning gage. Records from January to March, 1917, probably good; those from April to September, 1917, only fair, and discharge determinations for low stages should be used with caution.

The following discharge measurement was made by L. J. Hall:

February 27, 1917: Gage height, 3.23 feet (referred to original datum of gage); discharge, 572 second-feet.

Daily discharge, in second-feet, of Big Bear River near Red Bay, Ala., for the years ending Sept. 30, 1913–1917.

INDEX.

STREAM-GAGING STATIONS

AND

PUBLICATIONS RELATING TO WATER RESOURCES

PART III.—OHIO RIVER BASIN

STREAM-GAGING STATIONS AND PUBLICATIONS RELATING TO WATER RESOURCES.

INTRODUCTION.

Investigation of water resources by the United States Geological Survey has consisted in large part of measurements of the volume of flow of streams and studies of the conditions affecting that flow, but it has comprised also investigation of such closely allied subjects as irrigation, water storage, water powers, ground waters, and quality of waters. Most of the results of these investigations have been published in the series of water-supply papers, but some have appeared in the monographs, bulletins, professional papers, and annual reports.

The results of stream-flow measurements are now published annually in 12 parts, each part covering an area whose boundaries coincide with natural drainage features as indicated below:

Part I. North Atlantic slope basins.
II. South Atlantic slope and eastern Gulf of Mexico basins.
III. Ohio River basin.
IV. St. Lawrence River basin.
V. Upper Mississippi River and Hudson Bay basins.
VI. Missouri River basin.
VII. Lower Mississippi River basin.
VIII. Western Gulf of Mexico basins.
IX. Colorado River basin.
X. Great Basin.
XI. Pacific slope basins in California.
XII. North Pacific slope basins, in three parts:
A, Pacific slope basins in Washington and upper Columbia River basin.
B. Snake River basin.
C, Lower Columbia River basin and Pacific slope basins in Oregon.

HOW GOVERNMENT REPORTS MAY BE OBTAINED OR CONSULTED.

Water-supply papers and other publications of the United States Geological Survey containing data in regard to the water resources of the United States may be obtained or consulted as indicated below.

1. Copies may be obtained free of charge by applying to the Director of the Geological Survey, Washington, D. C. The edition printed for free distribution is, however, small and is soon exhausted.

2. Copies may be purchased at nominal cost from the Superintendent of Documents, Government Printing Office, Washington, D. C., who will, on application, furnish lists giving prices.

115805°——20——W S P 453——12

3. Sets of the reports may be consulted in the libraries of the principal cities in the United States.

4. Complete sets are available for consultation in the local offices of the water-resources branch of the Geological Survey, as follows:

Boston, Mass., 2500 Customhouse.
Albany, N. Y., 704 Journal Building.
Atlanta, Ga., Post Office Building.
Madison, Wis., care of Railroad Commission of Wisconsin.
Austin, Tex., Capitol Building.
Helena, Mont., Montana National Bank Building.
Boise, Idaho, 615 Idaho Building.
Topeka, Kans., 23 Federal Building.
Denver, Colo., 403 New Post Office Building.
Tucson, Ariz., University of Arizona.
Salt Lake City, Utah, 313 Federal Building.
Tacoma, Wash., 406 Federal Building.
Portland, Oreg., 606 Post Office Building.
San Francisco, Calif., 328 Customhouse.
Los Angeles, Calif., 619 Federal Building.
Honolulu, Hawaii, 25 Capitol Building.

A list of the Geological Survey's publications may be obtained by applying to the Director, United States Geological Survey, Washington, D. C.

STREAM-FLOW REPORTS.

Stream-flow records have been obtained at more than 4,240 points in the United States, and the data obtained have been published in the reports tabulated on page 2.

Stream-flow data in reports of the United States Geological Survey.

[A=Annual Report; B=Bulletin; W=Water-Supply Paper.]

Report.	Character of data.	Year.
10th A, pt. 2	Descriptive information only	
11th A, pt. 2	Monthly discharge and descriptive information	1884 to Sept., 1890.
12th A, pt. 2	do	1884 to June 30, 1891.
13th A, pt. 3	Mean discharge in second-feet	1884 to Dec. 31, 1892.
14th A, pt. 2	Monthly discharge (long-time records, 1871 to 1893)	1888 to Dec. 31, 1893.
B 131	Descriptions, measurements, gage heights, and ratings	1893 and 1894.
16th A, pt. 2	Descriptive information only	
B 140	Descriptions, measurements, gage heights, ratings, and monthly discharge (also many data covering earlier years).	1895.
W 11	Gage heights (also gage heights for earlier years)	1896.
18th A, pt. 4	Descriptions, measurements, ratings, and monthly discharge (also similar data for some earlier years).	1895 and 1896.
W 15	Descriptions, measurements, and gage heights, eastern United States, eastern Mississippi River, and Missouri River above junction with Kansas.	1897.
W 16	Descriptions, measurements, and gage heights, western Mississippi River below junction of Missouri and Platte, and western United States.	1897.
19th A, pt. 4	Descriptions, measurements, ratings, and monthly discharge (also some long-time records).	1897.
W 27	Measurements, ratings, and gage heights, eastern United States, eastern Mississippi River, and Missouri River.	1898.
W 28	Measurements, ratings, and gage heights, Arkansas River and western United States.	1898.
20th A, pt. 4	Monthly discharge (also for many earlier years)	1898.
W 35 to 39	Descriptions, measurements, gage heights, and ratings	1899.
21st A, pt. 4	Monthly discharge	1899.
W 47 to 52	Descriptions, measurements, gage heights, and ratings	1900.
22d A, pt. 4	Monthly discharge	1900.
W 65, 66	Descriptions, measurements, gage heights, and ratings	1901.
W 75	Monthly discharge	1901.
W 82 to 85	Complete data	1902.
W 97 to 100	do	1903.
W 124 to 135	do	1904.
W 165 to 178	do	1905.
W 201 to 214	do	1906.
W 241 to 252	do	1907–8.
W 261 to 272	do	1909.
W 281 to 292	do	1910.
W 301 to 312	do	1911.
W 321 to 332	do	1912.
W 351 to 362	do	1913.
W 381 to 394	do	1914.
W 401 to 414	do	1915.
W 431 to 444	do	1916.
W 451 to 464	do	1917.

NOTE.—No stream-flow data are given in the 15th and 17th annual reports.

The records at the most of the stations discussed in these reports extend over a series of years, and miscellaneous measurements at many points other than regular gaging stations have been made each year. An index of the reports containing records obtained prior to 1904 has been published in Water-Supply Paper 119.

The following table gives, by years and drainage basins, the numbers of the papers on surface-water supply published from 1899 to 1917. The data for any particular station will be found in the reports covering the years during which the station was maintained. For example, data from 1902 to 1917 for any station in the area covered by Part III are published in Water-Supply Papers 83, 98, 128, 169, 205, 243, 263, 283, 303, 323, 353, 383, 403, 433, and 453 which contain records for the Ohio River basin for those years.

Numbers of water-supply papers containing results of stream measurements, 1899–1917.

a Rating tables and index to Water-Supply Papers 35–39 contained in Water Supply Paper 39. Tables of monthly discharge for 1899 in Twenty-first Annual Report, Part IV.
b James River only.
c Gallatin River.
d Green and Gunnison rivers and Grand River above junction with Gunnison.
e Mohave River only.
f Kings and Kerns rivers and south Pacific slope basins.
g Rating tables and index to Water-Supply Papers 47–52 and data on precipitation, wells, and irrigation in California and Utah contained in Water-Supply Paper 52. Tables of monthly discharge for 1900 in Twenty-second Annual Report, Part IV.
h Wissahickon and Schuylkill rivers to James River.
i Scioto River.
j Loup and Platte rivers near Columbus, Nebr., and all tributaries below junction with Platte.
k Tributaries of Mississippi from east.
l Lake Ontario and tributaries to St. Lawrence River proper.
m Hudson Bay only.
n New England Rivers only.
o Hudson River to Delaware River, inclusive.
p Susquehanna River to Yadkin River, inclusive.
q Platte and Kansas Rivers.
r Great Basin in California, except Truckee and Carson river basins.
s Below junction with Gila.
t Rogue, Umpqua, and Siletz rivers only.

In these papers and in the following lists the stations are arranged in downstream order. The main stem of any river is determined by measuring or estimating its drainage area: That is, the headwater stream having the largest drainage area is considered the continuation of the main stream, and local changes in name and lake surface are disregarded. All stations from the source to the mouth of the main stem of the river are presented first, and the tributaries in regular order from source to mouth follow, the streams in each tributary basin being listed before those of the next basin below.

In exception to this rule the records for Mississippi River are given in four parts, as indicated on page VI, and the records for large lakes taken up are in order of streams around the rim of the lake.

Part III. OHIO RIVER BASIN.

PRINCIPAL STREAMS.

The Ohio River basin includes Ohio River with all its tributaries, the most important being Allegheny, Monongahela, Beaver, Muskingum, New (or Kanawha), Scioto, Miami, Kentucky, Wabash, Cumberland, and Tennessee rivers. The streams drain parts of the States of Alabama, Georgia, Illinois, Indiana, Kentucky, Maryland, Mississippi, New York, North Carolina, Ohio, Pennsylvania, Tennessee, Virginia, and West Virginia.

In addition to the list of gaging stations and the annotated list of publications relating specifically to the Ohio River basin, the following pages contain a similar list of reports that are of general interest in many sections and cover a wide range of hydrologic subjects, and also brief references to reports published by State and other organizations. (See pp. xix–xx.)

GAGING STATIONS.

NOTE.—Dash following a date indicates that the station was being maintained September 30, 1917. Period after date indicates discontinuance.

Allegheny River (head of Ohio River) at Red House, N. Y., 1903–
Allegheny River at Kittanning, Pa., 1904–1913.
Ohio River at Wheeling, W. Va., 1905–6.
  Conewango Creek:
    Chadakoin River (Chatauqua Lake outlet) near Jamestown, N. Y., 1904–5.
  Kiskiminitas River at Avonmore, Pa., 1907–1913.
  Kiskiminitas River at Salina, Pa., 1904–5.
    Blacklick Creek at Blacklick, Pa., 1904–1906; 1907–1913.
  Tygart River (head of Monongahela River) near Dailey, W. Va., 1915–
  Tygart River at Belington, W. Va., 1907–
  Tygart River at Fetterman, W. Va., 1907–
  Monongahela River at Lock 15, Hoult, W. Va., 1915–
  Monongahela River at Morgantown, W. Va., 1914–15.
  Monongahela River at Lock No. 4, Pa., 1886–1905. Flood-stage record only.
    Middle Fork at Midvale, W. Va., 1915–
    Buckhannon River at Hall, W. Va., 1907–1909; 1915–
    West Fork at Butcherville, W. Va., 1915–
    West Fork at Enterprise, W. Va., 1907–
      Elk Creek near Clarksburg, W. Va., 1910–
    Buffalo Creek at Barrackville, W. Va., 1907–8; 1915–
    Deckers Creek at Morgantown, W. Va., 1914–15.
    Cheat River near Parsons, W. Va., 1913–
    Cheat River at Rowlesburg, W. Va., 1912–
    Cheat River near Morgantown, W. Va., 1899–1900; 1902–1905; 1908–
      Blackwater River at Hendricks, W. Va., 1911–
      Shavers Fork at Parsons, W. Va., 1910–
      Big Sandy Creek at Rockville, W. Va., 1909–

Ohio River tributaries—Continued.
  Monongahela River tributaries—Continued.
    Youghiogheny River at Friendsville, Md., 1898–1904.
    Youghiogheny River at Confluence, Pa., 1904–1913.
      Casselman River at Markleton, Pa., 1913.
      Casselman River at Confluence, Pa., 1904–1913.
        Laurel Hill Creek at Ursina, Pa., 1913.
        Laurel Hill Creek at Confluence, Pa., 1904–1913.
      Indian Creek in Westmoreland County, Pa., 1892–93.
  Beaver River at Wampum, Pa., 1914.
    Mahoning River at Youngstown, Ohio, 1903–1906.
    Conoquenessing Creek near Ellwood, Pa., 1914.
  Little Beaver River near East Liverpool, Ohio, 1915–
  Yellow Creek at Hammondsville, Ohio, 1915–
  Cross Creek near Mingo Junction, Ohio, 1903.
  McMahon River at Steel, Ohio, 1903.
  Middle Island Creek at Little, W. Va., 1915–
  Little Muskingum River at Fay, Ohio, 1915–
  Muskingum River at Zanesville, Ohio, 1905–1912.
  Muskingum River at Frazier, Ohio, 1915–
  Muskingum River at Beverly, Ohio, 1915–
    Mohican River at Pomerene, Ohio, 1910–1913.
    Licking River at Pleasant Valley, Ohio, 1902–1906.
    Jonathan Creek at Powells, Ohio, 1902–3.
  Little Kanawha River at Glenville, W. Va., 1915–
  Little Kanawha River at Lock 4, Palestine, W. Va., 1915–
    South Fork of Hughes River at Macfarlan, W. Va., 1915–
    Hughes River at Cisko, W. Va., 1915–
  Hocking River at Athens, Ohio, 1915–
  New River, South Fork (head of New River, which in turn is head of Kanawha River) at New River, N. C., 1900–1901.
  New River, South Fork, near Crumpler, N. C., 1908–1916.
  New River near Oldtown, Va., 1900–1903.
  New River near Grayson, Va., 1908–1912.
  New River at Radford, Va., 1898–1906; 1907–1915.
  New River at Eggleston, Va., 1914–
  New River at Fayette, W. Va., 1895–1901; 1902–1904; 1908–1916.
  Kanawha River at Lock 2, Montgomery, W. Va., 1915–
    North Fork of New River, near Crumpler, N. C., 1908–1916.
    North Fork of New River at Weaversford, N. C., 1900–1901.
    Reed Creek at Grahams Forge, Va., 1908–1916.
    Big Reed Island Creek near Allisonia, Va., 1908–1916.
    Little River near Copper Valley, Va., 1908–1916.
    Walker Creek at Staffordsville, Va., 1908–1916.
    Wolf Creek near Narrows, Va., 1908–1916.
    Bluestone River at Lilly, W. Va., 1908–1916.
    Bluestone River near True, W. Va., 1911–12.
    Greenbrier River near Marlinton, W. Va., 1908–1916.
    Greenbrier River at Alderson, W. Va., 1895–1906; 1907–
    Gauley River at Allingdale, W. Va., 1908–1916.
    Gauley River near Summersville, W. Va., 1908–1916.
    Gauley River near Belva, W. Va., 1908–1916.
      Cherry River at Richwood, W. Va., 1908–1916.
      Meadow River near Russellville, W. Va., 1908–1916.

- Ohio River tributaries—Continued.
  - Kanawha River tributaries—Continued.
    - Elk River at Webster Springs, W. Va., 1908–1916.
    - Elk River at Gassaway, W. Va., 1908–1916.
    - Elk River at Clendenin, W. Va., 1908–1916.
    - Coal River at Brushton, W. Va., 1908–1916.
    - Coal River at Fuqua, W. Va., 1911–1916.
    - Coal River at Tornado, W. Va., 1908–1912.
      - Little Coal River at McCorkle, W. Va., 1915–
    - Pocotalico River at Sissonville, W. Va., 1908–1916.
  - Raccoon Creek at Adamsville, Ohio, 1915–
  - Guyandot River at Wilber, W. Va., 1915–
  - Guyandot River at Branchland, W. Va., 1915–
    - Mud River at Yates, W. Va., 1915–
  - Twelvepole Creek at Wayne, W. Va., 1915–
  - Levisa Fork (head of Big Sandy River) at Thelma, Ky., 1915–
    - Tug Fork at Kermit, W. Va., 1915–
    - Blaine Creek at Yatesville, Ky., 1915–
  - Scioto River near Columbus, Ohio, 1898–1901; 1903–1906.
  - Scioto River at Chillicothe, Ohio, 1914.
  - Scioto River at Waverly, Ohio, 1916–
    - Olentangy River near Columbus, Ohio, 1898–1901; 1903–1906.
  - Little Miami River near Morrow, Ohio, 1903.
  - Little Miami River at Loveland, Ohio, 1906.
  - Little Miami River at Miamiville, Ohio, 1915–
  - Little Miami River at Plainville, Ohio, 1914–1915.
    - East Fork Little Miami River at Perintown, Ohio, 1915–
  - Licking River at Farmers, Ky., 1915–
  - Licking River at Falmouth, Ky., 1914–1916.
  - Licking River at Catawba, Ky., 1916–
  - Licking River at Morning View, Ky., 1916.
    - South Fork of Licking River at Hayes, Ky., 1916–
    - South Fork of Licking River at Falmouth, Ky., 1915–16.
  - Mill Creek at Arlington Heights, Ohio, 1912–1916.
  - Mill Creek at Cincinnati, Ohio, 1912–13.
  - Miami River at Sidney, Ohio, 1914–
  - Miami River at Piqua, Ohio, 1913–
  - Miami River at Tadmor, Ohio, 1914–
  - Miami River at Dayton, Ohio, 1905–1909; 1913–
  - Miami River at Franklin, Ohio, 1916–
  - Miami River at Hamilton, Ohio, 1910–
  - Miami River at Venice, Ohio, 1915–
    - Loramie Creek at Lockington, Ohio, 1915–
    - Stillwater River at Pleasant Hill, Ohio, 1916–
    - Stillwater River near West Milton, Ohio, 1914–
    - Mad River near Springfield, Ohio, 1904–1906; 1914–
    - Mad River near Dayton, Ohio, 1914–
      - Buck Creek at Springfield, Ohio, 1914–
    - Twin Creek near Germantown, Ohio, 1914–
    - Fourmile Creek near Sevenmile, Ohio, 1914–
      - Sevenmile Creek at Sevenmile, Ohio, 1914–
    - Whitewater River at Brookville, Ind., 1915–
  - Kentucky River at Frankfort, Ky., 1905–6.
    - Dix River near Danville, Ky., 1905–6.
    - Dix River near Burgin, Ky., 1910–
    - Elkhorn Creek at Forks of Elkhorn, Ky., 1915–
    - Eagle Creek at Glencoe, Ky., 1915–

Ohio River tributaries—Continued.
- Rolling Fork of Salt River (head of Salt River) at New Haven, Ky., 1905–6.
- Green River at Munfordville, Ky., 1915–
- Wabash River at Logansport, Ind., 1903–1906.
- Wabash River at La Fayette, Ind., 1901–1903.
- Wabash River at Terre Haute, Ind., 1902–1904; 1905–6.
- Wabash River at Mount Carmel, Ill., 1909–1913.
  - Eel River at Logansport, Ind., 1903.
  - Tippecanoe River at Springboro, near Delphi, Ind., 1903–1906; 1908.
  - Vermilion River near Danville, Ill., 1914–
  - Embarrass River near Oakland, Ill., 1909–1912; 1914–15.
  - Embarrass River at Ste. Marie, Ill., 1909–1912; 1914–
  - White River, West Branch (head of White River) near Noblesville, Ind., 1915–
  - White River, West Branch at Indianapolis, Ind., 1904–1906.
    - Eel River at Cataract, Ind., 1903–1906.
    - East Branch of White River at Shoals, Ind., 1903–1906; 1909–1916.
  - Little Wabash River near Clay City, Ill., 1908–1912.
  - Little Wabash River at Wilcox, Ill., 1914–
  - Little Wabash River near Golden Gate, Ill., 1908–1912.
  - Little Wabash River at Carmi, Ill., 1908–1912.
    - Skillet Fork at Wayne City, Ill., 1908–1912; 1914–
    - Skillet Fork near Mill Shoals, Ill., 1908–1912.
- Cumberland River at Cumberland Falls, Ky., 1907–1911; 1915–
- Cumberland River at Burnside, Ky., 1915–
- Cumberland River at Nashville, Tenn., 1902–1904.
  - South Fork of Cumberland River at Nevelsville, Ky., 1915–
  - Caney Fork near Rock Island, Tenn., 1911–
    - Collins River near Rowland, Tenn., 1916–
- French Broad River (head of Tennessee River) at Rosman, N. C., 1907–1909.
- French Broad River at Horseshoe, N. C., 1904–1906.
- French Broad River at Asheville, N. C., 1895–
- French Broad River at Oldtown, near Newport, Tenn., 1900–1905; 1907.
- Tennessee River at Knoxville, Tenn., 1900–1912.
- Tennessee River at Chattanooga, Tenn., 1873–1913; 1915–
- Tennessee River at Florence, Ala., 1871–
- Tennessee River at Johnsonville, Tenn., 1875–
  - Davidson River near Davidson River, N. C., 1904–1909.
  - Little River at Calhoun, N. C., 1907–8.
  - Mills River, South Fork (head of Mills River), near Sitton, N. C., 1904–1909.
    - North Fork of Mills River at Pinkbed, N. C., 1904–1909.
  - Mud Creek at Naples, N. C., 1907.
  - Swannanoa River at Swannanoa, N. C., 1907–1909.
  - Swannanoa River at Biltmore, N. C., 1904.
  - Ivy River at Democrat, N. C., 1907.
  - Pigeon River at Canton, N. C., 1907–1909.
  - Pigeon River at Newport, Tenn., 1900–1901; 1903–1905; 1906–1909.
  - Nolichucky River at Chucky Valley, Tenn., 1900–1901.
  - Nolichucky River at Greenville, Tenn., 1903–1908.
    - North Toe River at Spruce Pine, N. C., 1907–8.
  - Holston River, South Fork (head of Holston River), near Chilhowie, Va., 1907–1909.
  - Holston River, South Fork, at Bluff City, Tenn., 1900–
  - Holston River near Rogersville, Tenn., 1902–
    - Middle Fork of Holston River at Chilhowie, Va., 1907–1909.
    - Watauga River at Butler, Tenn., 1900–1901.
    - Watauga River near Elizabethton, Tenn., 1903–1908.
      - Elk Creek at Lineback, Tenn., 1900–1901.

Ohio River tributaries—Continued.
 Tennessee River tributaries—Continued.
  Holston River tributaries—Continued.
   Roane Creek at Butler, Tenn., 1900–1901.
   Doe River at Blevins, Tenn., 1911–1915.
   Doe River at Valley Forge, Tenn., 1911–1916.
   Doe River at Elizabethton, Tenn., 1907–8; 1912.
   North Fork of Holston River at Saltville, Va., 1907–8.
  Little Tennessee River near Franklin, N. C., 1907–1910.
  Little Tennessee River at Judson, N. C., 1896–
  Little Tennessee River at McGhee, Tenn., 1905–1914.
   Cullasagee River at Cullasagee, N. C., 1907–1909.
   Nantahala River near Nantahala, N. C., 1907–1909.
   Tuckasegee River near East Laport, N. C., 1907–1909.
   Tuckasegee River at Bryson, N. C., 1897–
    Scott Creek near Dillsboro, N. C., 1907–8.
    Oconalufty River near Cherokee, N, C., 1907–8.
   Cheoah River at Millsaps, N. C., 1907–8.
  Clinch River at Clinchport, Va., 1907–1909.
  Hiwassee River near Hayesville, N. C., 1907–1909.
  Hiwassee River at Murphy, N. C., 1896–1917.
  Hiwassee River at Reliance, Tenn., 1900–1913.
  Hiwassee River at Charleston, Tenn., 1899–1902.
   Tusquitee Creek near Hayesville, N. C., 1907–1909.
   Valley River at Tomotla, N. C., 1904–1909; 1914–1917.
   Nottely River near Ranger, N. C., 1901–1905; 1914–1917.
   Toccoa River (head of Ocoee River) near Dial, Ga., 1907–8; 1913–
   Toccoa River near Morganton, Ga., 1898–1903; 1913–
   Ocoee River at McCays (Copper Hill), Tenn., 1903–1913.
   Ocoee River at McHarge, Tenn., 1917–
   Ocoee River at Emf, Tenn., 1913–
   Ocoee River at Parksville, Tenn., 1911–1916.
  Big Bear River near Red Bay, Ala., 1913–
  Elk River near Elkmont, Ala., 1904–1908.
  Duck River at Columbia, Tenn., 1904–1908.

REPORTS ON WATER RESOURCES OF THE OHIO RIVER BASIN.[1]

PUBLICATIONS OF UNITED STATES GEOLOGICAL SURVEY.

WATER-SUPPLY PAPERS.

Water-supply papers are distributed free by the Geological Survey as long as its stock lasts. An asterisk (*) indicates that this stock has been exhausted. Many of the papers marked in this way may, however, be purchased from the SUPERINTENDENT OF DOCUMENTS, WASHINGTON, D. C. Water-supply papers are of octavo size.

*21. Wells of northern Indiana, by Frank Leverett. 1899. 82 pp., 2 pls. (Continued in No. 26.)

Discusses by counties the glacial deposits and the sources of well waters; gives many well sections.

*24. Water resources of the State of New York, Part I, by G. W. Rafter. 1899. 99 pp., 13 pls. 15c.

*25. Water resources of the State of New York, Part II, by G. W. Rafter. 1899. 100 pp., 12 pls. 15c.

No. 24 contains descriptions of the principal rivers of New York and their more important tributaries, and data on temperature, precipitation, evaporation, and stream flow.

No. 25 contains discussion of water-storage projects on Genesee and Hudson rivers, power development at Niagara Falls, descriptions and early history of State canals, and a chapter on the use and value of the water power of the streams and canals: also brief discussion of the water yield of sand areas of Long Island.

[1] For stream-measurement reports see tables on p. VI.

*26. Wells of southern Indiana (continuation of No. 21), by Frank Leverett. 1899. 64 pp. 5c.

Discusses by counties the glacial deposits and the sources of well water; contains many well sections.

*44. Profiles of rivers in the United States, by Henry Gannett. 1901. 100 pp., 11 pls. 15c.

Gives elevations and distances along rivers of the United States, and brief descriptions of many of the streams, including Ohio River and a number of its tributaries.

*57. Preliminary list of deep borings in the United States, Part I (Alabama-Montana), by N. H. Darton. 1902. 60 pp. 5c.

*61. Preliminary list of deep borings in the United States, Part II (Nebraska-Wyoming), by N. H. Darton. 1902. 67 pp. 5c.

A second, revised, edition of Nos. 57 and 61 was published in 1905 as Water-Supply Paper 149 (q. v.).

62. Hydrography of the southern Appalachian Mountain region, Part I, by H. A. Pressey. 1902. 95 pp., 25 pls. 15c.

*63. Hydrography of the southern Appalachian Mountain region, Part II, by H. A. Pressey. 1902. pp. 96–190, pls. 26–44. 15c.

Nos. 62 and 63 describe in a general way the mountains, rivers, climate, forests, soil, vegetation, and mineral resources of the southern Appalachian Mountains, and then discuss in detail the drainage basins, giving for each an account of the physical features, rainfall, forests, minerals, transportation, discharge measurements, and water powers. Most of the streams described are tributary through Tennessee River to the Ohio, but Part II (No. 63) includes also descriptions of several streams in the south Atlantic slope and eastern Gulf of Mexico drainage basins.

79. Normal and polluted waters in northeastern United States, by M. O. Leighton. 1903. 192 pp. 10c.

Defines essential qualities of water for various uses, the impurities in rain, surface, and ground waters, the meaning and importance of sanitary analyses, and the principal sources of pollution; chiefly "a review of the more readily available records" of examination of water supplies derived from streams in the Merrimack, Connecticut, Housatonic, Delaware, and Ohio, River basins; contains many analyses.

91. The natural features and economic development of the Sandusky, Maumee, Muskingum, and Miami drainage areas in Ohio, by B. H. and M. S. Flynn. 1904. 130 pp. 10c.

Describes the topography, geology, and soils of the areas and discusses stream flow, dams, water powers, and public water supplies.

96. Destructive floods in the United States in 1903, by E. C. Murphy. 1904. 81 pp., 13 pls. 15c.

Contains notes on early floods in Mississippi Valley.

102. Contributions to the hydrology of eastern United States, 1903; M. L. Fuller, geologist in charge. 1904. 522 pp. 30c.

Contain brief reports on springs and wells of Alabama, Georgia, Tennessee, and Kentucky. The reports comprise tabulated well records giving information as to location, owner, depth, yield, head, etc., supplemented by notes as to elevation above sea, materials penetrated, temperature, use and quality; many miscellaneous analyses.

*103. A review of the laws forbidding pollution of inland waters in the United States, by E. B. Goodell. 1904. 120 pp. See 152.

Cites statutory restrictions of water pollution in Alabama, Indiana, Illinois, Kentucky, Maryland, New York, North Carolina, Ohio, Pennsylvania, Tennessee, Virginia, and West Virginia.

*107. Water powers of Alabama, with an appendix on stream measurements in Mississippi, by B. M. Hall. 1904. 253 pp., 9 pls. 20c.

Contains gage heights, rating tables, estimates of monthly discharge at stations on Tallapoosa, Coosa, Alabama, Cahaba, Black Warrior, Tombigbee, and Tennessee rivers and their tributaries; gives estimates and short descriptions of water powers.

110. Contributions to the hydrology of eastern United States, 1904; M. L. Fuller. geologist in charge. 1905. 211 pp., 5 pls. 10c. Contains:

Water resources of the Middlesboro-Harlan region of southeastern Kentucky, by George H. Ashley. Describes topographic features of the area and the water supply of Middlesboro and Pineville.

Water resources of the Cowee and Pisgah quadrangles, North Carolina, by Hoyt S. Gale. Discusses drainage, springs, and waters of one of the units of the geologic atlas of the United States.

113. The disposal of strawboard and oil-well wastes, by R. L. Sackett and Isaiah Bowman. 1905. 52 pp., 4pls. 5c.

Contains a brief report on the topography, drainage, geology, and the pollution of wells and streams by oil waste and brine in an area drained by Mississinewa River, a tributary of the Wabash.

*114. Underground waters of eastern United States; M. L. Fuller, geologist in charge, 1905. 285 pp., 18 pls. 25c.

Contains brief reports relating to Ohio River drainage areas, as follows:
Tennessee and Kentucky, by L. C. Glenn.
Ohio, by Frank Leverett.
Illinois, by Frank Leverett.
West Virginia, by M. L. Fuller.
Indiana, by Frank Leverett.
North Carolina, by M. L. Fuller.
South Carolina, by L. C. Glenn.
Georgia, by S. W. McCallie.
Alabama, by E. A. Smith.

Each of these reports describes the geology of the area in its relation to water supplies, notes the principal mineral springs, and gives list of pertinent publications.

115. River surveys and profiles made during 1903. arranged by W. C. Hall and J. C. Hoyt. 1905. 115 pp.,4 pls. 10c.

Contains results of surveys made to determine location of undeveloped power sites. Gives elevations and distances along Hiwassee, Nottely, and Toccoa rivers.

144. The normal distribution of chlorine in the natural waters of New York and New England, by D. D. Jackson. 1905. 31 pp., 5 pls. 10c.

Discusses common salt in coast and inland waters, salt as an index to pollution of streams and wells, the solutions and methods used in chlorine determinations, and the use of the normal chlorine map; gives charts and tables for chlorine in the New England States and New York.

145. Contributions to the hydrology of eastern United States, 1905; M. L. Fuller, geologist in charge. 1905. 220 pp., 6 pls. 10c.

Contains "Water resources of the Nicholas quadrangle, West Virginia," by George H. Ashley Describes topography, geology, and domestic water supply of the hilly region in central West Virginia, a little east of New and Kanawha rivers.

147. Destructive floods in United States in 1904, by E. C. Murphy and others. 1905. 206 pp., 18 pls. 15c.

Describes Wabash River flood, Indiana, causes of flood discharge, damage, and prevention of damage; also the drought in the Ohio River basin, its causes and effects; flood in Scottdale Valley, caused by failure of dam on Jacobs Creek (tributary to the Ohio through Youghiogheny River).

*149. Preliminary list of deep borings in the United States, second edition with additions, by N. H. Darton. 1905. 175 pp. 10c.

Gives by States (and within the States by counties); location, depth, diameter, yield, height of water, and other valuable information concerning wells 400 feet or more in depth; includes all wells listed in Water-Supply Papers 57 and 61; mentions also principal publications relating to deep borings.

*152. A review of the laws forbidding pollution of inland waters in the United States (second edition), by E. B. Goodell. 1905. 149 pp. 10c.

Cites statutory restrictions of water pollution in Alabama, Illinois, Indiana, Kentucky, Maryland, New York, North Carolina, Ohio, Pennsylvania, Tennessee, Virginia, and West Virginia.

159. Summary of the underground-water resources of Mississippi, by A. F. Crider and L. C. Johnson. 1906. 86 pp., 6 pls. 20c.

Describes geography, topography, and general geology of the State; discusses the source, depth of penetration, rate of percolation, and recovery of ground waters; artesian requisites, and special conditions in the Coastal Plain formations; gives notes on wells by counties, deep-well records, and selected records in detail; treats of sanitary aspect of wells and gives analyses.

*162. Destructive floods in the United States in 1905, with a discussion of flood discharge and frequency and an index to flood literature, by E. C. Murphy and others. 1906. 105 pp., 4 pls. 15c.

Gives accounts of floods on Allegheny and Ohio rivers, and estimates of flood discharge and frequency on Monongahela, Youghiogheny, and Tennessee rivers.

*164. Underground waters of Tennessee and Kentucky west of Tennessee River and of an adjacent area in Illinois, by L. C. Glenn. 1906. 173 pp., 7 pls. 25c.

Describes static level and uses of waters, artesian conditions, and source and properties of ground water; discusses topography, geology, and water resources by counties; gives logs of wells, analyses of waters, and bibliography of most important reports.

*197. Water resources of Georgia, by B. M. and M. R. Hall. 1907. 342 pp., 1 pl. 50c.

Describes topographic and geologic features of the State; discusses by drainage basins stream flow, river surveys, and water powers.

*233. Water resources of the Blue Grass region, Kentucky, by G. C. Matson, with a chapter on the quality of the waters, by Chase Palmer. 1909. 223 pp., 3 pls. 20c.

Describes the geologic formations, physiographic features, soils, and surface waters of the region; the source, conditions of occurrence, amount and recovery of the ground waters, collection and storage of rain water, municipal water supplies, and conditions in each county; discusses under "Quality" the industrial uses of the water, comparative hardness, and mineral and table waters; many analyses.

236. The quality of surface waters in the United States, Part I, Analyses of waters east of the one hundredth meridian, by R. B. Dole. 1909. 123 pp. 10c.

Describes collection of samples, method of examination, preparation of solutions, accuracy of estimates, and expression of analytical results; gives results of analyses of waters of Allegheny, Cumberland, Kentucky, Miami, Wabash, and Tennessee rivers and some of their tributaries.

*239. The quality of the surface waters of Illinois, by W. D. Collins. 1910. 94 pp., 3 pls. 10c.

Discusses the natural and economic features that determine the character of the streams; describes the larger drainage basins and the methods of collecting and analyzing the samples of water, and discusses each river in detail with reference to its source, course, and quality of water; includes short chapters on municipal supplies and industrial uses.

254. The underground waters of north-central Indiana, by S. R. Capps, with a chapter on the chemical character of the waters, by R. B. Dole. 1910. 279 pp., 7 pls. 40c.

Describes relief, drainage, vegetation, soils, and crops, industrial development, and geologic formations; source, movements, occurrence and volume of ground water: methods of well construction and lifting devices: discusses in detail for each county surface features and drainage; geology and ground water, city, village, and rural supplies, and gives records of wells and analyses of waters. Discusses also, under chemical character, methods of analyses and expression of results, mineral constituents, effect of the constituents on waters for domestic, industrial, and medicinal uses, methods of purification, chemical composition; many analyses and field assays

259. The underground waters of southwestern Ohio, by M. L. Fuller and F. G. Clapp, with a discussion of the chemical character of the waters, by R. B. Dole. 1912. 228 pp., 9 pls. 35c.

Describes the topography, climate, and geology of the region, the water-bearing formations, the source, mode of occurrence, and head of the waters, and municipal supplies; gives details by counties; discusses in supplement, under chemical character, method of analyses and expression of results, mineral constituents, effect of the constituents on waters for domestic, industrial, or medicinal uses, methods of purification, chemical composition; many analyses and field assays. The matter in the supplement was also published in Water-Supply Paper 254 (The underground waters of north-central Indiana).

334. The Ohio Valley flood of March-April, 1913 (including comparisons with some earlier floods), by A. H. Horton and H. J. Jackson. 1913. 96 pp., 22 pls. 20c.

Although relating specifically to floods in the Ohio Valley, this report discusses also the causes of floods and the prevention of damage by floods.

*364. Water analyses from the laboratory of the United States Geological Survey, tabulated by F. W. Clarke, chief chemist. 1914. 40 pp. 5c.

Contains analyses of spring and well waters from Pennsylvania, West Virginia, Kentucky, Tennessee, and Illinois, and of mine waters from Ducktown, Tenn.

ANNUAL REPORTS.

Each of the papers contained in the annual reports was also issued in separate forms.

Annual reports are distributed free by the Geological Survey as long as its stock lasts. An asterisk (*) indicates that this stock has been exhausted. Many of the papers so marked, however, may be purchased from the SUPERINTENDENT OF DOCUMENTS, WASHINGTON, D. C.

Fourteenth Annual Report of the United States Geological Survey, 1892–93, J. W. Powell, Director. 1893. (Pt. II, 1894.) 2 parts. *Pt. II. Accompanying papers, pp. xx, 597, 73 pls. $2.10. Contains:

*The potable waters of the eastern United States, by W. J. McGee, pp. 1–47. Discusses cistern water, stream waters, and ground waters, including mineral springs and artesian wells.

Seventeenth Annual Report of the United States Geological Survey, 1895–96, Charles D. Walcott, Director. 1896. 3 parts in 4 vols. *Pt. II. Economic geology and hydrography, pp. xxv, 864, 113 pls. $2.35. Contains:

*The water resources of Illinois, by Frank Leverett, pp. 695–849, pls. 106 to 113. Describes the physical features of the State, and the drainage basins, including tributaries of the Mississippi in western Illinois, and tributaries of the Wabash; discusses the rainfall and run-off, navigable waters and water powers, the wells supplying water for rural districts, and artesian wells; contains tabulated artesian well data and water analyses.

Eighteenth Annual Report of the United States Geological Survey, 1896–97, Charles D. Walcott, Director. 1897. (Pts. II and III, 1898.) 5 parts in 6 vols. *Pt. IV, Hydrography, pp. x, 756, 102 pls. $1.75. Contains:

*The water resources of Indiana and Ohio, by Frank Leverett, pp. 419–560, pls. 33 to 37. Describes the Wabash, Whitewater, Great Miami, Little Miami, Scioto, Hocking, Muskingum, and Beaver rivers and lesser tributaries of the Ohio in Indiana and Ohio, the streams discharging into Lake Erie and Lake Michigan, and streams flowing to the upper Mississippi through the Illinois; discusses shallow and drift wells, the flowing wells from the drift and deeper artesian wells, and gives records of wells at many of the cities; describes the mineral springs, and gives analyses of the waters; contains also tabulated lists of cities using surface waters for waterworks, and of cities and villages using shallow and deep well waters; discusses the source and quality of the city and village supplies; and gives precipitation tables for various points.

Nineteenth Annual Report of the United States Geological Survey, 1897–98, Charles D. Walcott, Director. 1898. (Pts. II, III, and V, 1899.) 6 parts in 7 vols. and separate case for maps with Pt. V. *Pt. IV, Hydrography, pp. viii, 814, 118 plates. $1.85. Contains:

*The rock waters of Ohio, by Edward Orton, pp. 633–717, pls. 71 to 73. Describes the principal geologic formations of Ohio and the waters from the different strata; discusses the flowing wells at various points and the artesian wells of pre-Glacial channels in Allen, Auglaize, and Mercer counties; discusses city and village supplies; gives analyses of waters from various formations.

MONOGRAPHS.

Monographs are of quarto size. They are not distributed free, but may be obtained from the Geological Survey or from the SUPERINTENDENT OF DOCUMENTS, WASHINGTON, D. C., at the prices indicated. An asterisk (*) indicates that the Survey's stock of the paper is exhausted.

41. Glacial formations and drainage features of the Erie and Ohio basins, by Frank Leverett. 1902. 802 pp., 26 pls. $1.75.

Treats of an area extending westward from Genessee Valley in New York across northwestern Pennsylvania and Ohio, central and southern Indiana, and southward from Lakes Ontario and Erie to the vicinity of Allegheny and Ohio rivers.

PROFESSIONAL PAPERS.

Professional papers are distributed free by the Geological Survey as long as its stock lasts. An asterisk (*) indicates that this stock has been exhausted. Many of the papers marked with an asterisk may, however, be purchased from the SUPERINTENDENT OF DOCUMENTS, WASHINGTON, D. C. Professional papers are of quarto size.

*37. The southern Appalachian forests, by H. B. Ayres and W. W. Ashe. 1905. 291 pp., 37 pls. 80c.

Describes the relief, drainage, climate, natural resources, scenery, and water supply of the southern Appalachian forests, the trees, shrubs, and rate of growth; gives details concerning forests by drainage basins, including New, Holston (southern tributaries of South Fork only) Watauga, Nolichucky, French Broad, Pigeon, Little Tennessee, Hiwassee, Tallulah-Chatooga Toxaway, Saluda, and First and Second Broad rivers, Catawba and Yadkin rivers, describing many of the tributaries of each of the master streams.

*72. Denudation and erosion in the southern Appalachian region and the Monongahela basin, by L. C. Glenn. 1911. 137 pp., 21 pls. 35c.

Describes the topography, geology, drainage, forests, climate and population, and transportation facilities of the region, the relation of agriculture, lumbering, mining, and power development to erosion and denudation, and the nature, effects, and remedies of erosion; gives details of conditions in Holston, Nolichucky, French Broad, Little Tennessee, and Hiwassee river basins, along Tennessee River proper, and in the basins of the Coosa-Alabama system, Chattahoochee, Savannah, Saluda, Broad, Catawba, Yadkin, New, and Monongahela rivers.

BULLETINS.

An asterisk (*) indicates that the Geological Survey's stock of the paper is exhausted. Many of the papers so marked may be purchased from the SUPERINTENDENT OF DOCUMENTS, WASHINGTON, D. C. Bulletins are of octavo size.

*264. Record of deep-well drilling for 1904, by M. L. Fuller, E. F. Lines, and A. C. Veatch. 1905. 106 pp. 10c.

Discusses the importance of accurate well records to the driller, to owners of oil, gas, and water wells, and to the geologist; describes the general method of work; gives tabulated records of wells in Illinois, Indiana, New York, Ohio, Pennsylvania, Tennessee, West Virginia, and Kentucky, and detailed records of wells in Delaware and Jay counties, Ind.; Greene, Warren, and Washington counties, Pa.; and Kanawha, Ritchie, and Wetzel counties, W. Va. These records were selected because they give definite stratigraphic information.

*298. Record of deep-well drilling for 1905, by M. L. Fuller and Samuel Sanford. 1906. 299 pp. 25c.

Gives an account of progress in the collection of well records and samples; contains tabulated records of wells in Alabama, Illinois, Indiana, Kentucky, New York, Ohio, Pennsylvania, Tennessee, Virginia, and West Virginia, and detailed records of wells in Madison County, Ala., Crawford County, Ill.; Delaware, Martin, Randolph, and Vanderburg counties, Ind.; Hopkins and Metcalfe counties, Ky.; Hocking, Noble, Tuscarawas, and Wayne counties, Ohio; Armstrong, Greene, Somerset, Warren, and Washington counties, Pa.; and Cabell, Harrison, Marion, Monongalia, Wayne, and Wetzel counties, W. Va. The wells of which detailed records are given were selected because they afford definite stratigraphic information.

GEOLOGIC FOLIOS.

Under the plan adopted for the preparation of a geologic map of the United States the entire area is divided into small quadrangles, bounded by certain meridians and parallels, and these quadrangles, which number several thousand, are separately surveyed and mapped.[1] The unit of survey is also the unit of publication, and the maps and description of each quadrangle are issued in the form of a folio. When all the folios are completed they will constitute the Geologic Atlas of the United States.

A folio is designated by the name of the principal town or of a prominent natural feature within the quadrangle. Each folio includes maps showing the topography, geology, underground structure, and mineral deposits of the area mapped and several pages of descriptive text. The text explains the maps and describes the topographic

[1] Index maps showing areas in the Ohio River basin covered by topographic maps and by geologic folios will be mailed on receipt of request addressed to the Director, U. S. Geological Survey, Washington, D. C.

and geologic features of the country and its mineral products. The topographic map shows roads, railroads, waterways, and, by contour lines, the shapes of the hills and valleys and the height above sea level of all points in the quadrangle. The areal-geology map shows the distribution of the various rocks at the surface. The structural-geology map shows the relations of the rocks to one another underground. The economic-geology map indicates the location of mineral deposits that are commercially valuable. The artesian-water map shows the depth to underground-water horizons. Economic-geology and artesian-water maps are included in folios if the conditions in the areas mapped warrant their publication. The folios are of special interest to students of geography and geology and are valuable as guides in the development and utilization of mineral resources.

The folios numbered from 1 to 163, inclusive, are published in only one form (18 by 22 inches), called the library edition. Some of the folios that bear numbers higher than 163 are published also in an octavo edition (6 by 9 inches). Owing to a fire in the Geological Survey building May 18, 1913, the stock of geologic folios was more or less damaged by fire and water, but many of the folios were usable. They are sold at the uniform price of 5 cents each, with no reduction for wholesale orders. This rate applies to folios in stock from 1 to 184, inclusive (except reprints); also to the library edition of folio 186. The library edition of folios 185, 187, and higher numbers sells for 25 cents a copy, except that some folios which contain an unusually large amount of matter sell at higher prices. The octavo edition of folio 185 and higher numbers sell for 50 cents a copy, except folio 193, which sells for 75 cents a copy. A discount of 40 per cent is allowed on an order for folios or for folios together with topographic maps amounting to $5 or more at the retail rate.

All the folios contain descriptions of the drainage of the quadrangles. The folios in the following list contain also brief discussions of the underground waters in connection with the economic resources of the areas and more or less information concerning the utilization of the water resources.

An asterisk (*) indicates that the stock of the folio is exhausted.

*16. Knoxville folio, Tennessee-North Carolina.

*67. Danville folio, Illinois-Indiana.

Discusses the shallow dug or open wells, the tubular wells, and the flowing wells; gives also tabulated data concerning depth, head, water-bearing bed, etc., of the wells in the quadrangle.

84. Ditney folio, Indiana. 5c.

90. Cranberry folio, North Carolina-Tennessee.

102. Indiana folio, Pennsylvania. 5c.

Indicates promising localities for artesian water.

105. Patoka folio, Indiana-Illinois. 5c.

Discusses the water supply of the streams, springs, wells, cisterns, and artificial ponds.

*121. Waynesburg folio, Pennsylvania.

123. Elders Ridge, Pennsylvania. 5c.

*124. Mount Mitchell, North Carolina-Tennessee.

Describes water powers and the various sources of water used for industrial and domestic supplies.

*144. Amity, Pennsylvania.

Gives a brief discussion of the water supply of the town of Washington.

*146. Rogersville, Pennsylvania.

*147. Pisgah, North Carolina-South Carolina.

*151. Roan Mountain, Tennessee-North Carolina.

*160. Accident-Grantsville, Maryland-Pennsylvania-West Virginia.

Notes possibility of obtaining artesian water.

172. Warren,[1] Pennsylvania-New York. 5c.
*174. Johnstown,[1] Pennsylvania. 5c.
Describes the city water supply at Johnstown and the water resources of the quadrangle in general.
176. Sewickley, Pennsylvania. 5c.
*177. Burgettstown-Carnegie,[2] Pennsylvania.
Contains partial well records.
180. Claysville, Pennsylvania. 5c.
184. Kenova, Kentucky-West Virginia-Ohio. 5c.
187. Ellijay, Georgia-North Carolina-Tennessee. 25c.
Contains brief paragraph on water power.
189. Barnesboro-Patton, Pennsylvania. 25c.
197. Columbus, Ohio. Library edition, 25c.; octavo edition, 50c.
Gives brief description of the water supply of Columbus and analyses of the mineral content of the water of Scioto River.

MISCELLANEOUS REPORTS.

Other Federal bureaus and State and other organizations have from time to time published reports relating to the water resources of the various sections of the country. Notable among those pertaining to the Ohio River basin are the reports of the Chief of Engineers, United States Army; the State geological surveys of Alabama, Illinois, Kentucky, North Carolina, Tennessee, and Virginia; the Illinois Water-Supply Commission and the Rivers and Lakes Commission of Illinois; the New York State Conservation Commission and State Water-Supply Commission; the Water-Supply Commission of Pennsylvania and the Pittsburgh Flood Commission; and the water-power report of the Tenth Census (vol. 17). The following reports deserve special mention.

The Mississippi and Ohio rivers, by Charles H. Ellet. 1853.

Report upon the physics and hydraulics of the Mississippi River, by A. A. Humphreys and H. L. Abbot. 1861.

Preliminary report on a part of the water powers of Alabama, by B. M. Hall: Alabama Geol. Survey Bull. 7, 1903.

The underground water resources of Alabama, by Eugene A. Smith: Alabama Geol. Survey Mon. 6, 1907.

Preliminary report on a part of the water powers of Georgia, compiled by B. M. Hall: Georgia Geol. Survey Bull. 3 A, 1896.

Preliminary report on the underground waters of Georgia, by S. W. McCallie: Georgia Geol. Survey Bull. 15, 1908.

The mineral content of Illinois waters, by Edward Bartow, J. A. Udden, S. W. Parr, and George T. Palmer: Illinois State Geol. Survey Bull. 10, 1909.

Chemical survey of the waters of Illinois, report for the years 1897-1902, by A. W. Palmer, with Geology of Illinois as related to its water supply, by Charles W. Rolfe: University of Illinois publications.

Chemical and biological survey of waters of Illinois, by Edward Bartow: University of Illinois publications 3, 6, 7, 1906-1909.

---

[1] Issued in two editions. (See p. xviii.) Specify which edition is wanted.
[2] Library edition out of stock.

Report upon the prevention of overflow of Little Wabash and Skillet Fork rivers, by W. J. McEathron and L. L. Hidinger. Rivers and Lakes Commission, 1911.

Papers on the water power of North Carolina, a preliminary report by George F. Swain: North Carolina Geol. Survey Bull. 8, 1899.

Report of the investigations into the purification of the Ohio River water for the improved water supply of the city of Cincinnati, Ohio; made by the board of trustees, commissioners of waterworks, Cincinnati, 1899.

Progress report on a plan of sewerage for the city of Cincinnati, 1912–13.

The mineral waters of Indiana, their location, origin, and character, by W. S. Blatchley: Indiana Dept. Geology and Nat. Res. Twenty-sixth Ann. Rept., 1901.

Report on the value of the Dix River as a source of water power, by August F. Foerste, and Supplementary report on Dix River, by August F. Foerste: Kentucky Geol. Survey Bull. 21, 1912.

Underground waters of Mississippi, a preliminary report, by W. N. Logan and W. R. Perkins: Mississippi Agr. Exper. Sta. Bull. 89.

Hydrology of the State of New York, by George W. Rafter: New York State Mus. Bull. 85, 1905.

A report to the mayor and city council on flood protection for the city of Columbus, Ohio, 1913.

Report of the filtration commission of the city of Pittsburgh, Pa., 1899.

The water powers of Tennessee, by J. A. Switzer, including a report on Doe River, by A. H. Horton: Tennessee Geol. Survey Bull. 17, 1914.

Hydrography of Virginia, by N. C. Grover and R. H. Bolster: Virginia Geol. Survey Bull. 3, 1906.

Surface water supply of Virginia, by G. C. Stevens: Virginia Geol. Survey Bull. 10, 1916.

Report of the Secretary of Agriculture in relation to the forests, rivers, and mountains of the Southern Appalachian region: 57th Congress, 1st sess., S. Doc. 84, 1902.

Many of these reports can be obtained by applying to the several commissions, and most of them can be consulted in the public libraries of the larger cities.

GEOLOGICAL SURVEY HYDROLOGIC REPORTS OF GENERAL INTEREST.

The following list comprises reports not readily classifiable by drainage basins and covering a wide range of hydrologic investigations:

WATER-SUPPLY PAPERS.

*1. Pumping water for irrigation, H. M. Wilson. 1896. 57 pp., 9 pls.

Describes pumps and motive powers, windmills, water wheels, and various kinds of engines; also storage reservoirs to retain pumped water until needed for irrigation.

*3. Sewage irrigation, by G. W. Rafter. 1897. 100 pp., 4 pls. (See Water-Supply Paper 22.) 10c.

Discusses methods of sewage disposal by intermittent filtration and by irrigation; describes utilization of sewage in Germany, England, and France, and sewage purification in the United States.

*8. Windmills for irrigation, by E. C. Murphy. 1897. 49 pp., 8 pls. 10c.

Gives results of experimental tests of windmills during the summer of 1896 in the vicinity of Garden, Kans.; describes instruments and methods and draws conclusions.

*14. New tests of certain pumps and water lifts used in irrigation, by O. P. Hood. 1898. 91 pp., 1 pl.

Discusses efficiency of pumps and water lifts of various types.

*20. Experiments with windmills, by T. O. Perry. 1899. 97 pp., 12 pls. 15c.

Includes tables and descriptions of wind wheels, compares wheels of several types, and discusses results.

*22. Sewage irrigation, Part II, by G. W. Rafter. 1899. 100 pp., 7 pls. 15c.

Gives résumé of Water-Supply Paper 3; discusses pollution of certain streams, experiments on purification of factory wastes in Massachusetts, value of commercial fertilizers, and describes American sewage-disposal plants by States; contains bibliography of publications relating to sewage utilization and disposal.

*41. The windmill: Its efficiency and economic use, Part I, by E. C. Murphy. 1901. 72 pp., 14 pls. 5c.

*42. The windmill: Its efficiency and economic use, Part II, by E. C. Murphy. 1901. 75 pp. (73–147), 2 pls. (15–16). 10c.

Nos. 41 and 42 give details of results of experimental tests with windmills of various types.

*43. Conveyance of water in irrigation canals, flumes, and pipes, by Samuel Fortier. 1901. 86 pp., 15 pls. 15c.

*56. Methods of stream measurement. 1901. 51 pp., 12 pls. 15c.

Describes the methods used by the Survey in 1901–2. (See also Nos. 64, 94, and 95.)

*64. Accuracy of stream measurements, by E. C. Murphy. 1902. 99 pp., 4 pls. (See No. 95.) 10c.

Describes methods of measuring velocity of water and of measuring and computing stream flow and compares results obtained with the different instruments and methods; describes also experiments and results at the Cornell University hydraulic laboratory. A second, enlarged edition published as Water-Supply Paper 95.

*67. The motions of underground waters, by C. S. Slichter. 1902. 106 pp., 8 pls. 15c.

Discusses origin, depth, and amount of ground waters; permeability of rocks and porosity of soils; causes, rates, and laws of motions of ground water; surface and deep zones of flow, and recovery of waters by open wells and artesian and deep wells; treats of the shape and position of the water table; gives simple methods of measuring yields of flowing wells; describes artesian wells at Savannah, Ga.

72. Sewage pollution in the metropolitan area near New York City and its effect on inland water resources, by M. O. Leighton. 1902. 75 pp., 8 pls. 10c.

Defines "normal" and "polluted" waters and discusses the damages resulting from pollution.

*80. The relation of rainfall to run-off, by G. W. Rafter. 1903. 104 pp. 10c.

Treats of measurements of rainfall and laws and measurements of stream flow; gives rainfall, run-off, and evaporation formulas; discusses effects of forests on rainfall and run-off.

87. Irrigation in India (second edition), by H. M. Wilson. 1903. 238 pp., 27 pls. 25c.

First edition was published in Part II of the Twelfth Annual Report.

93. Proceedings of first conference of engineers of Reclamation Service, with accompanying papers, compiled by F. H. Newell, chief engineer. 1904. 361 pp. 25c. [Requests for this report should be addressed to the United States Reclamation Service.]

Contains, the following papers of more or less general interest:
Limits of an irrigation project, by D. W. Ross.
Relation of Federal and State laws to irrigation, by Morris Bien.
Electrical transmission of power for pumping, by H. A. Storrs.
Correct design and stability of high masonary dams, by George Y. Wisner.
Irrigation surveys and the use of the plane table, by J. B. Lippincott.
The use of alkaline waters for irrigation, by Thomas H. Means.

*94. Hydrographic manual of the United States Geological Survey, prepared by E. C. Murphy, J. C. Hoyt, and G. B. Hollister. 1904. 76 pp., 3 pls. 10c.

Gives instruction for field and office work relating to measurements of stream flow by current meters. (See also No. 95.)

*95. Accuracy of stream measurements (second, enlarged edition), by E. C. Murphy. 1904. 169 pp., 6 pls.

Describes methods of measuring and computing stream flow and compares results derived from different instruments and methods. (See also No. 94.)

*103. A review of the laws forbidding pollution of inland waters in the United States, by E. B. Goodell. 1904. 120 pp. (See No. 152.)

Explains the legal principles under which antipollution statutes become operative, quotes court decisions to show authority for various deductions, and classifies according to scope the statutes enacted in the different States.

110. Contributions to the hydrology of eastern United States, 1904; M. L. Fuller, geologist in charge. 1905. 211 pp., 5 pls. 10c.

Contains the following reports of general interest. The scope of each paper is indicated by its title.
Description of underflow meter used in measuring the velocity and direction of underground water, by Charles S. Slichter.
The California or "stovepipe" method of well construction, by Charles S. Slichter.
Approximate methods of measuring the yield of flowing wells, by Charles S. Slichter.
Corrections necessary in accurate determination of flow from vertical well casings, from notes furnished by A. N. Talbot.
Experiment relating to problems of well contamination at Quitman, Ga., by S. W. McCallie.

113. The disposal of strawboard and oil-well wastes, by R. L. Sackett and Isaiah Bowman. 1905. 52 pp., 4 pls. 5c.

The first paper discusses the pollution of streams by sewage and by trade wastes, describes the manufacture of strawboard and gives results of various experiments in disposing of the waste. The second paper describes briefly the topography, drainage, and geology of the region about Marion, Ind., the contamination of rock wells and of streams by waste-oil and brine.

*114. Underground waters of eastern United States; M. L. Fuller, geologist in charge. 1905. 285 pp., 18 pls. 25c.

Contains report on "Occurrence of underground waters," by M. L. Fuller, discussing sources, amount, and temperature of waters, permeability and storage capacity of rocks, water-bearing formations, recovery of water by springs, wells, and pumps, essential conditions of artesian flows, and general conditions affecting ground waters in eastern United States.

119. Index to the hydrographic progress reports of the United States Geological Survey, 1888 to 1903, by J. C. Hoyt and B. D. Wood. 1905. 253 pp. 15c.

120. Bibliographic review and index of papers relating to underground waters published by the United States Geological Survey, 1879–1904, by M. L. Fuller. 1905. 128 pp. 10c.

*122. Relation of the law to underground waters, by D. W. Johnson. 1905. 55 pp. 5c.

Defines and classifies underground waters, gives common-law rules relating to their use, and cites State legislative acts affecting them.

140. Field measurements of the rate of movement of underground waters, by C. S. Slichter. 1905. 122 pp., 15 pls. 15c.

Discusses the capacity of sand to transmit water, describes measurements of underflow in Rio Hondo, San Gabriel, and Mohave River valleys, Calif., and on Long Island, N. Y.; gives results of tests of wells and pumping plants, and describes stovepipe method of well construction.

143. Experiments on steel-concrete pipes on a working scale, by J. H. Quinton. 1905. 61 pp., 4 pls. 5c.

Scope indicated by title.

145. Contributions to the hydrology of eastern United States, 1905; M. L. Fuller, geologist in charge. 1905. 220 pp., 6 pls. 10c.

Contains brief reports of general interest as follows:

Drainage of ponds into drilled wells, by Robert E. Horton. Discusses efficiency, cost, and capacity of drainage wells, and gives statistics of such wells in southern Michigan.

Construction of so-called fountain and geyser springs, by Myron L. Fuller.

A convenient gage for determining low artesian heads, by Myron L. Fuller.

146. Proceedings of second conference of engineers of the Reclamation Service with accompanying papers, compiled by F. H. Newell, chief engineer. 1905. 267 pp. 15c. [Requests for this report should be addressed to the United States Reclamation Service.]

Contains brief account of the organization of the hydrographic [water resources] branch and the Reclamation Service, reports of conferences and committees, circulars of instruction, and many brief reports on subjects closely related to reclamation, and a bibliography of techinical papers by members of the service. Of the papers read at the conference those listed below (scope indicated by title) are of more or less general interest:

Proposed State code of water laws, by Morris Bien.
Power engineering applied to irrigation problems, by O. H. Ensign.
Estimates on tunneling in irrigation projects, by A. L. Fellows.
Collection of stream-gaging data, by N. C. Grover.
Diamond-drill methods by G. A. Hammond.
Mean-velocity and area curves, by F. W. Hanna.
Importance of general hydrographic data concerning basins of streams gaged, by R. E. Horton.
Effect of aquatic vegetation on stream flow, by R. E. Horton.
Sanitary regulations governing construction camps, by M. O. Leighton.
Necessity of draining irrigated land, by Thomas H. Means.
Alkali soils, by Thomas H. Means.
Cost of stream-gaging work, by E. C. Murphy.
Equipment of a cable gaging station, by E. C. Murphy.
Silting of reservoirs, by W. M. Reed.
Farm-unit classification, by D. W. Ross.
Cost of power for pumping irrigating water, by H. A. Storrs.
Records of flow of current-meter gaging stations during the frozen season, by F. H. Tillinghast.

147. Destructive floods in United States in 1894, by E. C. Murphy and others. 206 pp., 18 pls. 15c.

Contains a brief account of "A method of computing cross-section area of waterways," including formulas for maximum discharge and areas of cross section.

*150. Weir experiments, coefficients, and formulas, by R. E. Horton. 1906. 189 pp., 38 pls. (See Water-Supply Paper 200.) 15c.

Scope indicated by title.

151. Field assay of water, by M. O. Leighton. 1905. 77 pp., 4 pls.

Discusses methods, instruments, and reagents used in determining turbidity, color, iron, chlorides, and hardness in connection with the studies of the quality of water in various parts of the United States.

*152. A review of the laws forbidding pollution of inland waters in the United States, second edition, by E. B. Goodell. 1905. 149 pp. 10c.

Scope indicated by title.

*155. Fluctuations of the water level in wells, with special reference to Long Island, N. Y., by A. C. Veatch. 1906. 83 pp., 9 pls. 25c.

Includes general discussion of fluctuations due to rainfall and evaporation, barometric changes, temperature changes, changes in rivers, changes in lake level, tidal changes, effects of settlement, irrigation, dams, ground-water developments, and to indeterminate causes.

*160. Underground-water papers; M. L. Fuller, geologist in charge. 1906. 104 pp., 1 pl.

Gives account of work in 1905, lists of publications relating to ground waters, and contains the following brief reports of general interest:

Significance of the term "artesian," by Myron L. Fuller.
Representation of wells and springs on maps, by Myron L. Fuller.
Total amount of free water in the earth's crust, by Myron L. Fuller.
Use of fluorescein in the study of underground water, by R. B. Dole.
Problems of water contamination, by Isaiah Bowman.
Instances of improvement of water in wells, by Myron L. Fuller.

*162. Destructive floods in the United States in 1905, with a discussion of flood discharge and frequency and an index to flood literature, by E. C. Murphy and others. 1906. 105 pp., 4 pls. 15c.

*163. Bibliographic review and index of underground-water literature published in the United States in 1905, by M. L. Fuller, F. G. Clapp, and B. L. Johnson. 1906. 130 pp. 15c.

Scope indicated by title.

*179. Prevention of stream pollution by distillery refuse, based on investigations at Lynchburg, Ohio, by Herman Stabler. 1906. 34 pp., 1 pl. 10c.

Describes grain distillation, treatment of slop, sources, character, and effects of effluents on streams; discusses filtration, precipitation, fermentation, and evaporation methods of disposal of wastes without pollution.

*180. Turbine water-wheel tests and power tables, by R. E. Horton. 1906. 134 pp., 2 pls. 20c.

Scope indicated by title.

*185. Investigations on the purification of Boston sewage, * * * with a history of the sewage problem, by C.-E. A. Winslow and E. B. Phelps. 1906. 163 pp. 25c.

Discusses composition, disposal, purification, and treatment of sewages and tendencies in sewage-disposal practice in England, Germany, and the United States; describes character of crude sewage at Boston, removal of suspended matter, treatment in septic tanks, and purification in intermittent sand filtration and coarse material; gives bibliography.

*186. Stream pollution by acid-iron wastes: a report based on investigations made at Shelby, Ohio, by Herman Stabler. 1906. 36 pp., 1 pl.

Gives history of pollution by acid-iron wastes at Shelby, Ohio, and resulting litigation; discusses effect of acid-iron liquors on sewage purification processes, recovery of copperas from acid-iron wastes, and other processes for removal of pickling liquor.

*187. Determination of stream flow during the frozen season, by H. K. Barrows and R. E. Horton. 1907. 93 pp., 1 pl.

Scope indicated by title.

*189. The prevention of stream pollution by strawboard waste, by E. B. Phelps. 1906. 29 pp., 2 pls.

Describes manufacture of strawboard, present and proposed methods of disposal of waste liquors, laboratory investigations of precipitation and sedimentation, and field studies of amounts and character of water used, raw material and finished product, and mechanical filtration.

*194. Pollution of Illinois and Mississippi rivers by Chicago sewage (a digest of the testimony taken in the case of the State of Missouri *v.* The State of Illinois and the Sanitary District of Chicago), by M. O. Leighton. 1907. 369 pp., 2 pls.

Scope indicated by amplification of title.

*200. Weir experiments, coefficients, and formulas (revision of paper No. 150), by R. E. Horton. 1907. 195 pp., 38 pls. 35c.

Scope indicated by title.

*226. The pollution of streams by sulphite-pulp waste, a study of possible remedies, by E. B. Phelps. 1908. 37 pp., 1 pl. 10c.

Describes manufacture of sulphite pulp, the waste liquors, and the experimental work leading to suggestions as to methods of preventing stream pollution.

*229. The disinfection of sewage and sewage filter effluents, with a chapter on the putrescibility and stability of sewage effluents, by E. B. Phelps. 1909. 91 pp., 1 pl. 15c.

Scope indicated by title.

*234. Papers on the conservation of water resources. 1909. 96 pp., 2 pls. 15c.

Contains the following papers, whose scope is indicated by their titles: Distribution of rainfall, by Henry Gannett; Floods, by M. O. Leighton; Developed water powers, compiled under the direction of W. M. Steuart, with discussion by M. O. Leighton; Undeveloped water powers, by M. O. Leighton; Irrigation, by F. H. Newell; Underground waters, by W. C. Mendenhall; Denudation, by R. B. Dole and Herman Stabler; Control of catchment areas, by H. N. Parker.

*235. The purification of some textile and other factory wastes, by Herman Stabler and G. H. Pratt. 1909. 76 pp. 10c.

Discusses waste waters from wool scouring, bleaching and dyeing cotton yarn, bleaching cotton piece goods, and manufacture of oleomargarine, fertilizer, and glue.

236. The quality of surface waters in the United States: Part I.—Analyses of waters east of the one hundredth meridian, by R. B. Dole. 1909. 123 pp. 10c.

Describes collection of samples, method of examination, preparation of solutions, accuracy of estimates, and expression of analytical results.

238. The public utility of water powers and their governmental regulation, by René Tavernier and M. O. Leighton. 1910. 161 pp. 15c.

Discusses hydraulic power and irrigation, French, Italian, and Swiss legislation relative to the development of water powers, and laws proposed in the French Parliament; reviews work of bureau of hydraulics and agricultural improvements of the French department of agriculture, and gives résumé of Federal and State water-power legislation in the United States.

*255. Underground waters for farm use, by M. L. Fuller. 1910. 58 pp., 17 pls. 15c.

Discusses rocks as sources of water supply and the relative safety of supplies from different materials; springs, and their protection; open or dug and deep wells, their location, yield, relative cost, protection, and safety; advantages and disadvantages of cisterns and combination wells and cisterns.

*257. Well-drilling methods, by Isaiah Bowman. 1911. 139 pp., 4 pls. 15c.

Discusses amount, distribution, and disposal of rainfall, water-bearing rocks, amount of ground water, artesian conditions, and oil and gas bearing formations; gives history of well drilling in Asia, Europe, and the United States; describes in detail the various methods and the machinery used; discusses loss of tools and geologic difficulties; contamination of well water and methods of prevention; tests of capacity and measurement of depth; and costs of sinking wells.

*258. Underground-water papers, 1910, by M. L. Fuller, F. G. Clapp, G. C. Matson, Samuel Sanford, and H. C. Wolff. 1911. 135 pp., 2 pls. 15c.

Contains the following papers (scope indicated by titles) of general interest:
Drainage by wells, by M. L. Fuller.
Freezing of wells and related phenomena, by M. L. Fuller.
Pollution of underground waters in limestone, by G. C. Matson.
Protection of shallow wells in sandy deposits, by M. L. Fuller.
Magnetic wells, by M. L. Fuller.

274. Some stream waters of the western United States, with chapters on sediment carried by the Rio Grande and the industrial application of water analyses, by Herman Stabler. 1911. 188 pp. 15c.

Describes collection of samples, plan of analytical work, and methods of analyses; discusses soap-consuming power of waters, water-softening, boiler waters, and waters for irrigation.

*315. The purification of public water supplies, by G. A. Johnson. 1913. 84 pp., 8 pls. 10c.

Discusses ground, lake, and river waters as public supplies, development of waterworks systems in the United States, water consumption, and typhoid fever; describes methods of filtration and sterilization of water, and municipal water softening.

*337. The effects of ice on stream flow, by William Glenn Hoyt. 1913. 71 pp., 7 pls. 15c.

Discusses methods of measuring water flow of streams.

*345. Contributions to the hydrology of the United States, 1914. N. C. Grover, chief hydraulic engineer. 1915. 225 pp., 17 pls. 30c. Contains:

*(e) A method of determining the daily discharge of rivers of variable slope, by M. R. Hall, W. E. Hall, and C. H. Pierce, pp. 53-65.

371. Equipment for current-meter gaging stations, by G. J. Lyon. 1915. 64 pp., 37 pls. 20c.

Describes methods of installing automatic and other gages and of constructing gage wells, shelters, and structures for making discharge measurements and artificial controls.

*375. Contributions to the hydrology of the United States, 1915. N. C. Grover, chief hydraulic engineer. 1916. 181 pp., 9 pls. 15c.

Contains three papers presented at the conference of engineers of the water-resources branch in December, 1914.

*(c) Relation of stream gaging to the science of hydraulics, by C. H. Pierce and R. W. Davenport, pp. 77-84.

(e) A method of correcting river discharge for changing stage, by B. E. Jones, pp. 117-130.

(f) Conditions requiring the use of automatic gages in obtaining stream-flow records, by C. H. Pierce, pp. 131-139.

*400. Contributions to the hydrology of the United States, 1916. N. C. Grover, chief hydraulic engineer. 1917. 108 pp., 7 pls. Contains:

(a) The people's interest in water-power resources, by G. O. Smith, pp. 1-8.

*(c) The measurement of silt-laden streams, by Raymond C. Pierce, pp. 39-51.

(d) Accuracy of stream-flow data, by N. C. Grover and J. C. Hoyt, pp. 53-59.

416. The divining rod, a history of water witching, with a bibliography, by A. J. Ellis. 1917. 59 pp. 10c.

A brief paper published "merely to furnish a reply to the numerous inquiries that are continually being received from all parts of the country" as to the efficacy of the divining rod for locating underground water.

*425. Contributions to the hydrology of the United States, 1917. W. C. Grover, chief hydraulic engineer. 1918. Contains:

*(c) Hydraulic conversion tables and convenient equivalents, pp. 71-94. 1917.

427. Bibliography and index of the publications of the United States Geological Survey relating to ground water, by O. E. Meinzer. 1918. 169 pp., 1 pl.

Includes publications prepared, in whole or part, by the Geological Survey that treat any phase of the subject of ground water or any subject directly applicable to ground water. Illustrated by map showing reports that cover specific areas more or less thoroughly.

ANNUAL REPORTS.

*Fifth Annual Report of the United States Geological Survey, 1883-84, J. W. Powell, Director. 1885. xxxvi, 469 pp., 58 pls. $2.25. Contains:

*The requisite and qualifying conditions of artesian wells, by T. C. Chamberlin, pp. 125-173 pl. 21. Scope indicated by title.

*Twelfth Annual Report of the United States Geological Survey, 1890–91, J. W. Powell, Director. 1891. 2 parts. *Pt. II, Irrigation, xviii, 576 pp., 93 pls. $2. Contains:

*Irrigation in India, by H. M. Wilson, pp. 363–561, pls. 107 to 146. (See Water-Supply Paper 87.)

Thirteenth Annual Report of the United States Geological Survey, 1891–92, J. W. Powell, Director. 1892. (Pts. II and III, 1893.) 3 parts. *Pt. III, Irrigation, xi, 486 pp., 77 pls. $1.85. Contains:

*American irrigation engineering, by H. M. Wilson, pp. 101–349, pls. 111 to 146. Discusses the economic aspects of irrigation, alkaline drainage, silt and sedimentation; gives brief history of legislation; describes perennial canals in Idaho-California, Wyoming, and Arizona; discusses water-storage at reservoirs of the California and other projects, subsurface sources of supply, pumping, and subirrigation.

Fourteenth Annual Report of the United States Geological Survey, 1892–93, J. W. Powell, Director. 1893. (Pt. II, 1894.) 2 parts. *Pt. II, Accompanying papers, xx, 597 pp., 73 pls. $2.10. Contains:

*The potable waters of the eastern United States, by W. J. McGee, pp. 1–47. Discusses cistern water, stream waters, and ground waters, including mineral springs and artesian wells.

*Natural mineral waters of the United States, by A. C. Peale, pp. 49–88, pls. 3 and 4. Discusses the origin and flow of mineral springs, the source of mineralization, thermal springs, the chemical composition and analysis of spring waters, geographic distribution, and the utilization of mineral waters; gives a list of American mineral spring resorts; contains also some analyses.

Nineteenth Annual Report of the United States Geological Survey, 1897–98, Charles D. Walcott, Director. 1898. (Parts II, III, and V, 1899.) 6 parts in 7 vols. and separate case for maps with Pt. V. *Pt. II, Papers chiefly of a theoretic nature, v. 958 pp., 172 pls. $2.65. Contains:

*Principles and conditions of the movements of ground water, by F. H. King, pp. 59–294, pls. 6 to 16. Discusses the amount of water stored in sandstone, in soil, and in other rocks, the depth to which ground water penetrates; gravitational, thermal, and capillary movements of ground waters, and the configuration of the ground-water surface; gives the results of experimental investigations on the flow of air and water through a rigid, porous medium, and through sands, sandstones, and silts; discusses results obtained by other investigators, and summarizes results of observations; discusses also rate of flow of water through sand and rock, the growth of rivers, rate of filtration through soil, interference of wells, etc.

*Theoretical investigation of the motion of ground waters, by C. S. Slichter, pp. 295–384, pl. 17. Scope indicated by title.

PROFESSIONAL PAPERS.

86. The transportation of débris by running water, by G. K. Gilbert, based on experiments made with the assistance of E. C. Murphy. 1914. 263 pp., 3 pls. 70c.

The results of an investigation which was carried on in a specially equipped laboratory at Berkeley, Calif., and was undertaken for the purpose of learning "the laws which control the movement of bed load and especially to determine how the quantity of load is related to the stream slope and discharge and to the degree of comminution of the débris."

A highly technical report.

105. Hydraulic-mining débris in the Sierra Nevada, by G. K. Gilbert. 154 pp., 34 pls. 1917. 50c.

Presents the results of an investigation undertaken by the United States Geological Survey in response to a memorial from the California Miners' Association asking that a particular study be made of portions of the Sacramento and San Joaquin valleys affected by detritus from torrential streams. The report deals largely with geologic and physiographic aspects of the subject, traces the physical effects, past and future, of the hydraulic mining of earlier decades, the similar effects which certain other industries induce through stimulation of the erosion of the soil, and the influence of the restriction of the area of inundation by the construction of levees. Suggests cooperation by several interests for the control of the streams now carrying heavy loads of débris.

BULLETINS.

*32. Lists and analyses of the mineral springs of the United States (a preliminary study), by A. C. Peale. 1886. 235 pp.

Defines mineral waters, lists the springs by States, and gives tables of analyses.

*319. Summary of the controlling factors of artesian flows, by Myron L. Fuller. 1908. 10c.

Describes underground reservoirs, the sources of ground waters, the confining agents, the primary and modifying factors of artesian circulation, the essential and modifying factors of artesian flow, and typical artesian systems.

*479. The geochemical interpretation of water analyses, by Chase Palmer. 1911. 31 pp. 5c.

Discusses the expression of chemical analyses, the chemical character of water, and the properties of natural waters; gives a classification of waters based on property values and reacting values, and discusses the character of the waters of certain rivers as interpreted directly from the results of analyses; discusses also the relation of water properties to geologic formations, silica in river water, and the character of the water of the Mississippi and the Great Lakes and St. Lawrence River as indicated by chemical analyses.

695. The data of geochemistry (fourth edition), by F. W. Clarke. 1920. 832 pp. 45c.

Earlier editions were published as Bulletins 330, 491, and 616. Contains a discussion of the statement and interpretation of water analyses and a chapter on "Mineral wells and springs" (pp. 175–211). Discusses the definition and classification of mineral waters, changes in the composition of water, deposits of calcareous, ocherous, and siliceous materials made by water, vadose and juvenile waters, and thermal springs in relation to volcanism. Describes the different kinds of ground water and gives typical analyses. Includes a brief bibliography of papers containing water analyses.

INDEX BY AREAS AND SUBJECTS.

[A—Annual Reports; M—Monograph; B—Bulletin; P—Professional Paper; W—Water-Supply Paper; G F—Geologic folio.]

[1] Many of the reports contain brief subject bibliographies. See abstracts.
[2] Many analyses of river, spring, and well waters are scattered through publications, as noted in abstracts.

SURFACE WATER SUPPLY OF ST. LAWRENCE RIVER BASIN, 1917.

AUTHORIZATION AND SCOPE OF WORK.

This volume is one of a series of 14 reports presenting results of measurements of flow made on streams in the United States during the year ending September 30, 1917.

The data presented in these reports were collected by the United States Geological Survey under the following authority contained in the organic law (20 Stat. L., p. 394):

Provided, That this officer [the Director] shall have the direction of the Geological Survey and the classification of public lands and examination of the geological structure, mineral resources, and products of the national domain.

The work was begun in 1888 in connection with special studies relating to irrigation in the arid West. Since the fiscal year ending June 30, 1895, successive sundry-civil bills passed by Congress have carried the following item and appropriations:

For gaging the streams and determining the water supply of the United States, and for the investigation of underground currents and artesian wells, and for the preparation of reports upon the best methods of utilizing the water resources.

Annual appropriations for the fiscal years ending June 30, 1895–1917.

1895	$12,500
1896	20,000
1897 to 1900, inclusive	50,000
1901 to 1902, inclusive	100,000
1903 to 1906, inclusive	200,000
1907	150,000
1908 to 1910, inclusive	100,000
1911 to 1917, inclusive	150,000

In the execution of the work many private and State organizations have cooperated either by furnishing data or by assisting in collecting data. Acknowledgements for cooperation of the first kind are made in connection with the description of each station affected; cooperation of the second kind is acknowledged on page 9.

Measurements of stream flow have been made at about 4,240 points in the United States and also at many points in Alaska and the Hawaiian Islands. In July, 1917, 1,180 gaging stations were being maintained by the Survey and the cooperating organizations. Many miscellaneous discharge measurements are made at other points. In connection with this work data were also collected in regard to precipitation, evaporation, storage reservoirs, river profiles, and water power in many sections of the country and will be made available in water-supply papers from time to time. Information in regard to publications relating to water resources is presented in the appendix to this report.

DEFINITION OF TERMS.

The volume of water flowing in a stream—the "run-off" or "discharge"—is expressed in various terms, each of which has become associated with a certain class of work. These terms may be divided into two groups—(1) those that represent a rate of flow, as second-feet, gallons per minute, miner's inches, and discharge in second-feet per square mile, and (2) those that represent the actual quantity of water, as run-off in depth in inches, acre-feet, and millions of cubic feet. The principal terms used in this series of reports are second-feet per square mile, run-off in inches, and acre-feet. They may be defined as follows:

"Second-feet" is an abbreviation for "cubic feet per second." A second-foot is the rate of discharge of water flowing in a channel of rectangular cross section 1 foot wide and 1 foot deep at an average velocity of 1 foot per second. It is generally used as a fundamental unit from which others are computed.

"Second-feet per square mile" is the average number of cubic feet of water flowing per second from each square mile of area drained, on the assumption that the run-off is distributed uniformly both as regards time and area.

"Run-off (depth in inches)" is the depth to which an area would be covered if all the water flowing from it in a given period were uniformly distributed on the surface. It is used for comparing run-off with rainfall, which is usually expressed in depth in inches.

An "acre-foot," equivalent to 43,560 cubic feet, is the quantity required to cover an acre to the depth of 1 foot. The term is commonly used in connection with storage for irrigation.

The following terms not in common use are here defined:

"Stage-discharge relation," an abbreviation for the term "relation of gage height to discharge."

"Control," a term used to designate the section or sections of the stream below the gage which determines the stage-discharge relation at the gage. It should be noted that the control may not be the same section or sections at all stages.

The "point of zero flow" for a gaging station is that point on the gage—the gage height—to which the surface of the river would fall if there were no flow.

EXPLANATION OF DATA.

The data presented in this report cover the year beginning October 1, 1916, and ending September 30, 1917. At the first of January in most parts of the United States much of the precipitation in the preceding three months is stored as ground water, in the form of snow, or in ponds, lakes, and swamps, and this stored water passes off in the streams during the spring break-up; at the end of September, on the other hand, the only stored water available for run-off is possibly a small quantity in the ground; therefore the run-off for a year beginning October 1, is practically all derived from precipitation in that year.

The base data collected at gaging stations (Pl. I, *B*) consist of records of stage, measurements of discharge, and general information used to supplement the gage heights and discharge measurements in determining the daily flow. The records of stage are obtained either from direct readings on a staff gage or from a water-stage recorder (Pl. II) that gives a continuous record of the fluctuations. Measurements of discharge are made with a current meter by the general methods outlined in standard textbooks on the measurement of river discharge.

From the discharge measurements rating tables are prepared that give the discharge for any stage, and these rating tables, when applied to the gage heights, give the daily discharge from which the monthly and yearly mean discharge is determined.

The data presented for each gaging station in the area covered by this report comprise a description of the station, a table giving results of discharge measurements, a table showing the daily discharge of the stream, and a table of monthly and yearly discharge and run-off.

If the base data are insufficient to determine the daily discharge, tables giving daily gage heights and results of discharge measurements are published.

The description of the station gives, in addition to statements regarding location and equipment, information in regard to any conditions that may affect the constancy of the stage-discharge relation, covering such subjects as the occurrence of ice, the use of the stream for log driving, shifting of channel, and the cause and effect of backwater; it gives also information as to diversions that decrease the flow at the gage, artificial regulation, maximum and minimum recorded stages, and the accuracy of the records.

The table of daily discharge gives, in general, the discharge in second-feet corresponding to the mean of the gage heights read each day. At stations on streams subject to sudden or rapid dirunal fluctuation the discharge obtained from the rating table and the mean daily gage height may not be the true mean discharge for the day. If such stations are equipped with water-stage recorders the mean daily discharge is obtained by averaging the discharge at regular intervals during the day or by use of the discharge integrator, an instrument operating on the principle of the planimeter and containing as an essential element the rating curve of the station.

In the table of monthly discharge the column headed "Maximum" gives the mean flow for the day when the mean gage height was highest. As the gage height is the mean for the day, it does not indicate correctly the stage when the water surface was at crest height and the corresponding discharge was consequently larger than given in the maximum column. Likewise in the column headed "Minimum" the quantity given is the mean flow for the day when the mean gage height was lowest. The column headed "Mean" is the average flow in cubic feet for each second during the month. On this average flow computations recorded in the remaining columns, which are defined on page 6, are based.

ACCURACY OF FIELD DATA AND COMPUTED RESULTS.

The accuracy of stream-flow data depends primarily (1) on the permanency of the stage-discharge relation and (2) on the accuracy of observation of stage, measurements of flow, and interpretation of records.

A paragraph in the description of the station or footnotes added to the tables gives information regarding the (1) permanence of the stage-discharge relation, (2) precision with which the discharge rating curve is defined, (3) refinement of gage readings, (4) frequency of gage readings, and (5) methods of applying daily gage heights to the rating table to obtain the daily discharge.[1]

For the rating tables "well defined" indicates, in general, that the rating is probably accurate within 5 per cent; "fairly well defined," within 10 per cent; "poorly defined," within 15 to 25 per cent. These notes are very general and are based on the plotting of the individual measurements with reference to the mean rating curve.

The monthly means for any station may represent with high accuracy the quantity of water flowing past the gage, but the figures showing discharge per square mile and depth of run-off in inches may be subject to gross errors caused by the inclusion of large noncontributing districts in the measured drainage area, by lack of information concerning water diverted for irrigation or other use, or by inability to interpret the effect of artificial regulation of the flow of the river above the station. "Second-feet per square mile" and "run-off (depth in inches)" are therefore not computed if such errors appear probable. The computations are also omitted for

[1] For a more detailed discussion of the accuracy of stream-flow data see Grover, N. C., and Hoyt, J. C., Accuracy of stream-flow data: U. S. Geol. Survey Water-Supply Paper 400, pp. 53–59, 1916.

stations on streams draining areas in which the annual rainfall is less than 20 inches. All figures representing "second-feet per square mile" and "run-off (depth in inches)" previously published by the Survey should be used with caution because of possible inherent sources of error not known to the Survey.

The table of monthly discharge gives only a general idea of the flow at the station and should not be used for other than preliminary estimates; the tables of daily discharge allow more detailed studies of the variation in flow. It should be borne in mind, however, that the observations in each succeeding year may be expected to throw new light on data previously published.

COOPERATION.

The work in Minnesota during the year ending September 30, 1917, was done with State cooperation under terms of an act of the legislature of 1909 as embodied in joint resolution 19, which reads as follows:

Whereas the water supplies, water powers, navigation of our rivers, drainage of our lands, and the sanitary condition of our streams and their watersheds generally form one great asset and present one great problem: Therefore be it

Resolved by the house of representatives, the senate concurring, That the State Drainage Commission be, and is hereby, directed to investigate progress in other States toward the solution of said problem in such States, to investigate and determine the nature of said problem in this State.

The work was carried on in conjunction with the State Drainage Commission, E. V. Willard, acting State drainage engineer.

The work in Wisconsin during the year ending September 30, 1917, was done in cooperation with the Railroad Commission of Wisconsin, C. M. Larson, chief engineer, and at certain stations with the following organizations: Menominee & Marinette Light & Traction Co., Edward Daniell, general manager (Menominee River below Koss, Mich.); United States Army Engineer Corps (Wolf River at New London) and Fox River at Rapide Croche Dam; United States Indian Office (Wolf River at Keshenas).

The station on Little Calumet River at Harvey, Ill., was maintained in cooperation with the State of Illinois through the Rivers and Lakes Commission until June 30, 1917, and the Division of Waterways of the Department of Public Works, after that date, and with the sanitary district of Chicago.

The gage reader for Huron River at Flat Rock, Mich., was paid by the Eastern Michigan Edison Co., Washtenaw division, Ann Arbor, Mich.

Work in the State of New York has been conducted under cooperative agreements with the State engineer and surveyor, and since July 1, 1911, with the division of inland waters of the State Conservation Commission as provided by an act of the State legislature.

The water-stage recorder on Genesee River at Rochester, N. Y., was inspected by an employee of the Rochester Railway & Light Co. Water-stage recorder on Raquette River at Piercefield, N. Y., was inspected by an employee of the International Paper Co.

The work in Vermont has been carried on in cooperation with the the State of Vermont, Horace F. Graham, governor, and Herbert M. McIntosh, State engineer, and at certain stations in cooperation with the following organizations and individuals: Vermont Marble Co. (Otter Creek at Middlebury); the department of civil engineering of Norwich University (Dog River at Northfield); Charles T. Middlebrook, consulting engineer, Albany, N. Y. (Green River at Garfield), Newport Electric Light Co. (Clyde River at West Derby).

DIVISION OF WORK.

Data for stations in the Lake Superior and Lake Michigan drainage basins in Minnesota and Wisconsin were collected and prepared for publication under the direction of W. G. Hoyt, district engineer, assisted by S. B. Soulé, H. C. Beckman, E. L. Williams, R. B. Kilgore, F. W. Huels, and J. P. Schwada.

Data for stations in Lake Michigan drainage basins in Illinois were collected and prepared for publication, under the general direction of W. G. Hoyt, district Engineer, by H. C. Beckman, assisted by A. M. Wahl, H. S. Wahl, and Marcia Towle.

For stations in the Lake Huron, the Lake Michigan, and the Lake Erie drainage basins in Michigan, data were collected and prepared for publication under the direction of A. H. Horton, district engineer; assisted by B. J. Peterson.

Data for stations in the St. Lawrence drainage basin in New York were collected and prepared for publication under the direction of C. C. Covert, district engineer, assisted by O. W. Hartwell, E. D. Burchard, A. H. Davison, J. W. Moulton, W. A. James, and Helen Kimmey.

Data for stations in Vermont were collected and prepared for publication under the direction of C. H. Pierce, district engineer, assisted by H. W. Fear, Hardin Thweatt, H. H. Khachadoorian, M. R. Stackpole, and Hope Hearn.

The manuscript was assembled by B. J. Peterson.

GAGING-STATION RECORDS.

STREAMS TRIBUTARY TO LAKE SUPERIOR.

POPLAR RIVER AT LUTSEN, MINN.

LOCATION.—In sec. 34, T. 60 N., R. 3 W., near post office of Lutsen, Cook County, about 750 feet above mouth of river and same distance below State highway bridge.

DRAINAGE AREA.—144 square miles.

RECORDS AVAILABLE.—August 22, 1912, to September 30, 1917, when station was discontinued. May 6 to November 4, 1911 (gage heights only), at point about 350 feet downstream from present site.

GAGE.—Vertical staff bolted to rock wall of right bank of stream, in pool between two distinct falls; read by C. A. A. Nelson. Gage used prior to August 22, 1912, was a vertical staff gage attached to stump on right bank opposite lower point of easterly of two islands that divide flow into three channels. No determined relation between the two gages.

DISCHARGE MEASUREMENTS.—Made by wading or from a boat about 500 feet below the gage.

CHANNEL AND CONTROL.—Crest of falls below gage constitutes control. Channel at this point is solid rock. Banks not subject to overflow. Point of zero flow, gage-height −0.35 foot.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 3.72 feet at 6 p. m. June 19 (discharge, 756 second-feet); minimum stage recorded, 0.85 foot March 7–22 (discharge, 19 second-feet).

1912–1917: Maximum state recorded, 4.7 feet at 6 p. m. April 25, 1916 (discharge, 1,390 second-feet); minimum stage recorded, 0.80 foot January 4, February 8 and 13, 1913 (discharge, 18 second-feet).

ICE.—Stage-discharge relation not seriously affected by ice; open-channel rating curve assumed applicable.

REGULATION.—Flow in former years controlled to some extent by two dams above the station, the nearest being that of the National Paper & Pulp Co., 2½ miles above mouth of river, but it is believed that the flow for the last three years was entirely natural.

ACCURACY.—Stage-discharge relation permanent. Rating curve well defined between 18 and 1,040 second-feet. Gage read to quarter-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records excellent.

No discharge measurements were made at this station during the year.

Daily discharge, in second-feet, of Poplar River at Lutsen, Minn., for the year ending Sept. 30, 1917.

WHITEFACE RIVER BELOW MEADOWLANDS, MINN.

LOCATION.—In sec. 26, T. 53 N., R. 19 W., in St. Louis County, half a mile below beginning of a decided rapids, 1½ miles below Duluth, Missabe & Northern Railway bridge; 2½ miles below highway bridge on line between secs. 14 and 23, T. 53 N., R. 19 W., at which station on Whiteface River at Meadowlands was located; 4 miles below mouth of Little Whiteface River, which enters from left, and 8 miles above confluence of Whiteface and St. Louis Rivers.

DRAINAGE AREA.—446 square miles.

RECORDS AVAILABLE.—April 28, 1912, to September 30, 1917, when station was discontinued. Records June 7, 1909, to Nov. 9, 1912, collected at the station at Meadowlands, 2½ miles upstream.

GAGE.—Chain gage attached to a horizontal timber fastened to two trees on left bank of river, near residence of A. A. Jochim; used for all readings since November 8, 1914; read by A. A. Jochim. Chain gage attached to a horizontal timber fastened to two trees on the same bank but 300 feet upstream from the present gage was used from April 28, 1912, to November 7, 1914. Present gage was set so as to read the same as the former one at a stage of 2.85 feet.

DISCHARGE MEASUREMENTS.—Made from the Duluth, Missabe & Northern Railway bridge or by wading near gage.

CHANNEL AND CONTROL.—Bed of stream consists of heavy gravel and rock; practically permanent. Right bank is rather low and is overflowed at extremely high stages; left bank high and not subject to overflow. A decided rapids a short distance below the gage constitutes the control. Another rapids, above the gage, is frequently obstructed by logs, but when there is sufficient water to carry them over this rapid they are generally carried also over the lower rapids, so that the control is seldom obstructed.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 4.05 feet July 21 (discharge, 589 second-feet); minimum stage recorded, 1.98 feet at 7 p. m. September 26 (discharge, about 27 second-feet).

1909–1917: Maximum stage recorded, 12.0 feet April 21, 1916 (discharge, 5,880 second-feet); minimum stage recorded, 1.6 feet at 8.20 a. m. August 31, 1916 (discharge 15 second-feet). Open-water periods only; minimum flow probably much lower at times during the winter.

ICE.—Stage-discharge relation seriously affected by ice; observations discontinued during the winter.

REGULATION.—Flow controlled to a large extent by logging dams above the stations. Operation of gates to these dams causes a fluctuation in stage of several feet at the gaging station.

ACCURACY.—Stage-discharge relation probably permanent except as affected by logs and ice. Two rating curves used, one, applicable October 1 to November 18, 1916, fairly well defined above 92 second-feet; the other, applicable April 15 to September 30, 1917, poorly defined throughout. Gage read to quarter-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Mean daily gage height, as determined from two readings daily subject to some error on account of rather rapid fluctuation in stage occasioned by regulation of flow for log driving. Open-water records at medium and high stage fair to good; low-water records subject to error.

Discharge measurements of Whiteface River below Meadowlands, Minn., during the year ending Sept. 30, 1917.

August	286	60	153	.343	.40
September	156	28	70.3	.158	.18

NOTE.—Records of monthly discharge for August and September, 1916, supersede those published in Water-Supply Paper 434, p. 16.

CLOQUET RIVER AT INDEPENDENCE, MINN.

LOCATION.—In sec. 26, T. 52 N., R. 17 W., at highway bridge at Independence, St. Louis County, just below small tributary entering from right.

DRAINAGE AREA.—698 square miles.

RECORDS AVAILABLE.—June 28, 1909, to September 30, 1917, when station was discontinued.

GAGE.—Chain gage attached to upstream handrail of bridge, near left bank of stream; read by Theodore Haakensen. Gage used prior to October 13, 1915, was a vertical staff attached to upstream end of an old log bulkhead, immediately under the bridge and at the left bank.

DISCHARGE MEASUREMENTS.—Made from bridge or by wading about one-fourth mile below gage.

CHANNEL AND CONTROL.—Heavy gravel and rock; practically permanent. Banks not subject to overflow.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 8.4 feet October 19 (discharge, 3,650 second-feet); minimum stage recorded, 4.08 feet April 16, 17, 18 (discharge, about 78 second-feet).

1909–1917: Maximum stage recorded, 9.58 feet June 1, 1911 (discharge, 6,010 second-feet); minimum stage recorded, 3.90 feet July 20, 21, 22, 1911 (discharge, 54 second-feet). The Great Northern Power Co. reported there was no discharge from Fish Lake and Island Lake reservoirs April 6–20 and December 1, 1915; discharge at Independence estimated at 10 second-feet.

ICE.—Stage-discharge relation seriously affected by ice; observations discontinued during the winter. Since January, 1913, the determination of monthly mean discharge during winter periods has been based on discharge at outlet of Fish Lake reservoir on Cloquet River, in sec. 15, T. 52 N., R. 15 W., and from Island Lake reservoir on the Beaver River, in sec. 29, T. 52 N., R. 15 W.

REGULATION.—Cloquet River is used extensively for log driving, and the run-off from the greater part of the drainage area above Independence is controlled by logging dams. The operation of these dams causes rapid fluctuations in stage which may amount to several feet in 24 hours.

ACCURACY.—Stage-discharge relation permanent except as affected by ice and possibly by logs. Two rating curves used during year, both well defined between 128 and 4,690 second-feet. Gage read to quarter-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Mean daily gage height determined from two readings daily subject to considerable error on account of rapid fluctuation in stage occasioned by regulation of flow for log driving; records are therefore only roughly approximate to fair.

COOPERATION.—Records of flow from logging reservoirs December 9 to April 7 furnished by Great Northern Power Co., of Duluth.

Discharge measurements of Cloquet River at Independence, Minn., during the year ending Sept. 30, 1917.

BRULE RIVER NEAR BRULE, WIS.

Location.—About sec. 26, T. 48 N., R. 10 W., at Brule Outing Club, Douglas County, 4½ miles downstream from Brule and 9 miles above mouth of river.

Drainage area.—162 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

Records available.—March 19, 1914, to February 28, 1917, when station was discontinued.

Gage.—Vertical staff; low-water section, reading from 0 to 7.9 feet, fastened to downstream side of Brule Outing Club boat landing; high-water section, reading from 8.0 to 9.9 feet, fastened to tree on shore end of landing; read by Charles Leppanen.

Discharge measurements.—Made from a boat held in place by a wire across the river below the gage, or by wading. All measurements are made about 200 feet below gage section.

Channel and control.—Bed composed of gravel. One channel at all stages. Control formed by head of rapids below gage. Banks wooded; not subject to overflow.

Extremes of discharge.—Maximum stage recorded during year, 3.18 feet October 21 (discharge, 220 second-feet); minimum discharge, February 28, 134 second-feet (determined by current-meter measurement).

1914–1917: Maximum stage recorded, 6.2 feet April 21, 1916 (discharge, 1,490 second-feet); minimum stage recorded, 2.75 feet at 7 a. m. March 20, 1914 (discharge, 115 second-feet).

Ice.—Stage-discharge relation affected by ice.

Regulation.—None.

Accuracy.—Stage-discharge relation permanent except as affected by ice. Rating curve well defined between 145 and 1,370 second-feet. Gage read once daily, to quarter-tenths. Daily discharge ascertained by applying daily gage height to rating table, except for periods when stage-discharge relation was affected by ice, for which periods it was obtained by applying to rating curve daily gage height corrected for effect of ice by means of discharge measurements, observer's notes, and weather records. Open-water records good; winter records fair.

Discharge measurements of Brule River near Brule, Wis., during the year ending Sept. 30, 1917.

BAD RIVER NEAR ODANAH, WIS.

LOCATION.—In sec. 25, T. 47 N., R. 3 W., 8 miles upstream from Odanah, Ashland County, 12 miles above mouth. Potato River enters from right about 8 miles above station.

DRAINAGE AREA.—607 square miles (measured on map issued by Wisconsin Geological & Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

RECORDS AVAILABLE.—July 31, 1914, to September 30, 1917.

GAGE.—Stevens continuous water-stage recorder, installed March 31, 1915, over a wooden well, just above first falls above the mouth of river. A Gurley water-stage recorder at the same site was used July 31, 1914, to March 31, 1915.

DISCHARGE MEASUREMENTS.—Made from a cable about 700 feet upstream from the gage.

CHANNEL AND CONTROL.—Bed of channel is sand and gravel. Rock outcrops at the beginning of rapids about 200 feet below the gage form a permanent control. During log-driving periods logs may collect on the outcrop and cause backwater at the gage. Right bank high and not subject to overflow; left bank of medium height and may be overflowed by extremely high water.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 4.05 feet at 9 a. m. April 21 (discharge, 4,060 second-feet); minimum discharge somewhat less than 90 second-feet, in February.

1914–1917: Maximum stage recorded, 6.66 feet at 1 a. m. April 22, 1916 (discharge, 12,200 second-feet); minimum discharge occurred in February, 1917.

ICE.—Stage-discharge relation seriously affected by ice.

REGULATION.—A number of small reservoirs are operated during the early spring and summer as an aid to log driving. During such periods the stage may fluctuate rapidly.

ACCURACY.—Stage-discharge relation fairly permanent except when affected by ice. Rating curve well defined between 80 and 7,270 second-feet; extended above 7,270 second-feet and may be subject to considerable error. Operation of water-stage recorder only fairly satisfactory from October 1 until ice formed; record continuous from April 16 to September 30. Daily discharge October 1 to April 15 ascertained by applying to rating table mean daily gage height obtained by planimeter from recorder graph except for the following periods: October 6–12 and October 2 to November 15, discharge was estimated from records of flow in adjoining drainage basins; December 14 to April 15 (stage-discharge relation affected by ice), discharge determined from current-meter measurements and comparison with records of flow of streams in adjacent drainage basins; discharge April 16 to September 30 obtained by discharge integrator. Open-water records good except those based on estimates, which are fair; winter records roughly approximate.

Discharge measurements of Bad River near Odanah, Wis., during the year ending Sept. 30, 1917.

STREAMS TRIBUTARY TO LAKE MICHIGAN.

MENOMINEE RIVER BELOW KOSS, MICH.

LOCATION.—In sec. 5, T. 33 N., R. 23 E., at "Grand Rapids," about 4 miles below Koss, Marinette County, Mich., and 3 miles west of Ingalls, Mich. Little Cedar River, draining an area entirely in Michigan, enters from the left about half a mile below the station.

DRAINAGE AREA.—3,790 square miles.

RECORDS AVAILABLE.—July 1, 1913, to September 30, 1917.

DISCHARGE.—The flow is computed by the Menominee & Marinette Light & Traction Co., of Menominee, Mich., as follows: Each hour the load on the generators is noted and gage heights are read of the head and tail water to determine the head on the spillway of the dam and the acting head on the turbines. The flow through the turbines for each hour is taken from a table giving the discharge corresponding to load and head. The flow over the spillway is taken from a table computed from a weir formula. When water is wasted through the gates the magnitude and duration of the gate openings are noted and the quantity wasted is determined from computed tables. The sum of the hourly flow through the turbines and over the spillway, plus the quantity wasted through the gates, divided by the number of seconds in 24 hours, gives the average discharge in second-feet for the day. No account is taken of the water passing through the exciter turbine, nor waste over the "trash gate" at the power house. This quanity is, however, relatively small.

EXTREMES OF DISCHARGE.—Maximum daily discharge recorded during year, 13,800 second-feet April 24; minimum daily discharge recorded, 1,550 second-feet February 21.

1913–1917: Maximum daily discharge recorded, 23,200 second-feet, April 23 and 25, 1916; minimum daily discharge recorded, 1,000 second-feet, June 14, 1914.

REGULATION.—Above the station are the following power plants: Sturgeon Falls, owned by Penn. Iron Mining Co., 50 miles; Little Quinnesec, owned by Kimberly Clark Co., 57 miles; Upper Quinnesec, owned by Oliver Iron Mining Co., 62 miles; Twin Falls, owned by Peninsular Power Co. With the exception of the Kimberly Clark dam at Little Quinnesec, the dams furnish power for utility and mining uses, so that the flow past the dams is comparatively uniform. The Kimberly Clark dam is used for paper mills and regulates the flow on Sundays and holidays. The effect of this dam is felt at the stations generally on Tuesdays. The monthly flow should represent the natural flow.

ACCURACY.—No current-meter measurements have been made by the Survey engineers at this plant, but records of measurements made at Koss, Mich., during the year ending September 30, 1914, show a close comparison with the discharge as determined at the power house.

COOPERATION.—Daily discharge records furnished monthly by Edward Daniell, general manager of the Menominee & Marinette Light & Traction Co.

Daily discharge, in second-feet, of Menominee River below Koss, Mich., for the year ending Sept. 30, 1917.

NOTE.—Monthly and yearly discharge computed by engineers of the United States Geological Survey from records of daily discharge furnished by Menominee & Marinette Light & Traction Co.

PINE RIVER NEAR FLORENCE, WIS.

LOCATION.—In secs. 23 and 26, T. 39 N., R. 17 E., at highway bridge 8 miles southwest of Florence, Florence County, and 12 miles above mouth of river. Popple River enters from right about 200 feet above station.

DRAINAGE AREA.—488[a] square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

RECORDS AVAILABLE.—January 22, 1914, to September 30, 1917.

GAGE.—Chain gage fastened to guard rail on upstream side of bridge; read by William Taft.

DISCHARGE MEASUREMENTS.—Made from upstream side of bridge or by wading.

CHANNEL AND CONTROL.—Coarse gravel and stones. Left bank high; not subject to overflow; extremely high water may overflow right bank around approach to bridge.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 6.90 feet at noon, June 8 (discharge, 2,460 second-feet); minimum estimated discharge 135 second-feet in January and February.

1914–1917: Maximum recorded stage, 9.25 feet at noon, April 23, 1916 (discharge, about 4,520 second-feet); minimum recorded stage, 1.6 feet, September 6 and 7, 1915 (discharge, about 118 second-feet).

ICE.—Stage-discharge relation seriously affected by ice.

REGULATION.—River not used for log driving during year. Gates of a dam below remained open throughout the year.

ACCURACY.—Stage-discharge relation practically permanent; rating curve fairly well defined between 200 and 418 second-feet and well defined between 418 and 1,540 second feet; extension of curve below 200 and above 1,540 second-feet may be subject to considerable error. Gage read once daily to half-tenths. Daily discharge ascertained by applying daily gage height to rating table, except for period when stage-discharge relation was affected by ice, for which it was obtained from results of current-meter measurements, observer's notes, and weather records. Open-water records good except for extreme high and low stages; winter records fair.

Discharge measurements of Pine River near Florence, Wis., during the year ending Sept. 30, 1917.

[Made by R. B. Kilgore.]

Date.	Gage height.	Discharge.	Date.	Gage height.	Discharge.
	Feet.	*Sec.-ft.*		*Feet.*	*Sec.-ft.*
Jan. 1[b]	2.90	177	Mar. 5[a]	3.22	173
30[b]	3.00	179	June 25	4.30	1,060

[a] Supersedes figure published in previous reports. Revision based on the fact that Kentuck Lake discharges into Brule River, rather than into Pine River.

[b] Complete ice cover.

Daily discharge, in second-feet, of Pine River near Florence, Wis., for the year ending Sept. 30, 1917.

PIKE RIVER AT AMBERG, WIS.

LOCATION.—In sec. 15, T. 35 N., R. 21 E., at Chicago, Milwaukee & St. Paul Railway bridge half a mile south of Amberg, Marinette County, immediately below junction of two branches of Pike River, and about 11 miles above mouth.

DRAINAGE AREA.—240 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale 1 inch= 6 miles).

RECORDS AVAILABLE.—February 26, 1914, to September 30, 1917.

GAGE.—Chain gage fastened to guard rail on upstream side of bridge; read by Frank Bunce.

DISCHARGE MEASUREMENTS.—Made by wading or from a highway bridge a quarter of a mile downstream from the bridge to which the gage is attached.

CHANNEL AND CONTROL.—Solid rock and some loose granite boulders. Bed permanent but very rough at gage. Banks medium high; not subject to overflow.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 4.5 feet, 8.30 a. m. June 9 (discharge 1,120 second-feet); estimated minimum discharge, 120 second-feet, during January and February.

1914–1917: Maximum stage recorded, 4.65 feet at 8.10 p. m. July 14, 1914 (discharge 1,200 second-feet); minimum stage recorded, 1.55 feet September 7, 1915 (discharge, 109 second-feet).

REGULATION.—No dams are at present in operation above this station, flow natural.

ACCURACY.—Stage-discharge relation permanent except when affected by ice. Rating curve well defined between 180 and 1,120 second-feet. Gage read to quarter-tenths, once daily. Daily discharge ascertained by applying daily gage height to rating table, except for period when stage-discharge relation was affected by ice, for which it was ascertained from current meter measurements, observer's notes, and weather records. Open-water records excellent except for extremely high stages, for which they are good. Records for winter period fair.

Discharge measurements of Pike River at Amberg, Wis., during the year ending Sept. 30, 1917.

[Made by R. B. Kilgore.]

PESHTIGO RIVER AT HIGH FALLS, NEAR CRIVITZ, WIS.

LOCATION.—In sec. 1, T. 32 N., R. 18 E., at High Falls, near Crivitz, Marinette County, about a quarter of a mile downstream from power house of Wisconsin Public Service Co., 1 mile upstream from Thunder River (coming in from the right), and 15 miles by road northwest of Crivitz.

DRAINAGE AREA.—520[1] square miles (measured on Wisconsin Geological & Natural History Survey map, edition of 1911; scale: 1 inch=6 miles).

RECORDS AVAILABLE.—October 1, 1912, to September 30, 1917.

GAGE.—Barrett and Lawrence water-stage recorder set over a wooden well about 15 feet from the left bank and quarter of a mile downstream from power house; well is protected from floating logs by a large boulder.

DISCHARGE MEASUREMENTS.—Made from cable half a mile below gage.

CHANNEL AND CONTROL.—Banks at control and measuring section are high and not subject to overflow. Control for gage at low stages is a small gravel riffle about 50 feet downstream from the gage; apparently drowned out at medium and high stages, when control is probably formed by some point farther downstream.

EXTREMES OF DISCHARGE.—Maximum mean daily discharge during the year, 2,590 second-feet; minimum mean discharge, 104 second-feet January 7.

1912–1917: Maximum stage, from water-stage recorder, 7.2 feet, May 13, 1916 (discharge, 3,480 second-feet); minimum stage, 1.1 feet at 5 p. m. March 21, 1915 (discharge, 54 second-feet). Owing to artificial regulation extremes given do not represent the natural flow.

ICE.—Because of the relatively warm water in the large service reservoir ice does not form on the river in the vicinity of the gage; open-water rating curve used throughout year.

REGULATION.—Flow controlled by operation of the power plant. During log-driving seasons large and sudden fluctuations are caused by the operation of logging and sluice gates. The fluctuation due to changes in load are relatively small. The mean monthly flow does not represent the natural flow because of storage in the service reservoir.

ACCURACY.—Stage-discharge relation permanent; not affected by ice. Rating curve well defined between 145 and 3,980 second-feet. During periods when recording gage was in operation discharge ascertained by averaging the results obtained by applying gage heights for hourly or other regular intervals to the rating table; for period when gage was not in operation (see footnote to table of daily discharge) discharge determined from power-plant records. From the data available the power-plant records are believed to be accurate within 5 per cent.

The following discharge measurement was made by R. B. Kilgore:

June 23, 1917: Gage height, 3.37 feet; discharge, 1,150 second-feet.

---

[1] Supersedes figure published in previous reports.

Daily discharge, in second-feet, of Peshtigo River at High Falls, near Crivitz, Wis., for the year ending Sept. 30, 1917.

OCONTO RIVER NEAR GILLETT, WIS.

LOCATION.—In sec. 34, T. 28 N., R. 18 E., at highway bridge 2½ miles southeast of Gillett, Oconto County, and about 27 miles above mouth of river.

DRAINAGE AREA.—678 square miles (measured on Wisconsin Geological and Natural History Survey Map, edition of 1911; scale, 1 inch=6 miles).

RECORDS AVAILABLE.—June 7, 1906, to March 30, 1909; January 6, 1914, to September 30, 1917.

GAGE.—Chain gage attached to iron railing on upstream side of bridge; read by Miss Nettie Gilbertson. Zero of gage used January 6, 1914, to September 30, 1917, is 4 feet above that of gage used June 7, 1906, to March 31, 1909.

DISCHARGE MEASUREMENTS.—Made from upstream side of bridge.

CHANNEL AND CONTROL.—Gravel; fairly permanent; left bank medium high and not subject to overflow; right bank may overflow during extreme flood stages and water flow around the end of the bridge.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 5.7 feet, at 3.30 p. m. April 2 (discharge estimated, because of ice, 2,870 second-feet); estimated minimum discharge, 305 second-feet, January 24 to February 1.

1906–1917: Maximum stage recorded, 5.3 feet at 3.30 p. m. April 25, 1916 (discharge 3,220 second-feet); minimum open-water discharge, 95 second-feet January 3 and 6, 1907.

ICE.—Stage-discharge relation affected by ice.

REGULATION.—A dam above the station stores water to float logs during the spring; except when this dam is in operation flow at the gage is natural.

ACCURACY.—Stage-discharge relation practically permanent except as affected by ice. Rating curve well defined between 239 and 1,790 second-feet. Gage read to quarter-tenths once daily. Daily discharge ascertained by applying daily gage height to rating table, except for period when stage-discharge relation was affected by ice, for which it was obtained by applying to rating curve mean daily gage height corrected for effect of ice by means of discharge measurements, observer's notes, and weather records. Open-water records good, except for extreme flood stages, for which they are only fair; winter records fair.

Discharge measurements of Oconto River near Gillett, Wis., during the year ending Sept. 30, 1917.

FOX RIVER AT RAPIDE CROCHE DAM, NEAR WRIGHTSTOWN, WIS.

LOCATION.—At Rapide Croche dam, in sec. 4, T. 21 N., R. 19 E., 2 miles upstream from Wrightstown, Brown County, 19 miles downstream from Lake Winnebago, and 20 miles upstream from mouth of river at Green Bay.

RECORDS AVAILABLE.—March 3, 1896, to September 30, 1917. Daily-discharge records for this station, 1896–1914, were published by the Wisconsin Railroad Commission in a report entitled "Water-power report to the Legislature, 1915." The records published in this report have since been found to be considerably in error and should not be used. See "Determination of flow."

DRAINAGE AREA.—6,150 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

DETERMINATION OF DISCHARGE.—The dam is owned and operated by the United States Army Engineers to aid navigation, and the flow is computed by the United States Army Engineers as follows: The dam is made of timber and is equipped with 4 needle sluice gates which are used only in times of high water. A vertical staff gage at the lower end of the canal leading to the lock and about a quarter of a mile below the dam is read five times daily at 7 a. m., 9 a. m., 12 noon, 3 p. m., and 6 p. m. The mean flow for the day is computed from a formula using the 5 gage heights for the day, assuming gradual changes in gage height between the readings, and weighting the different gage heights by elapsed time. Prior to 1917 determinations of daily discharge were based on tables derived from theoretical formulas for flow over a sharp-crested weir and through the sluice gates. During 1917 discharge measurements were made by engineers of the United States Geological Survey from a cable a short distance downstream from the dam. Seven measurements were made with the four sluices closed and eight with all sluices open. The measured discharge varied from 1,000 to 13,000 second-feet. Curves based on the discharge measurements show that the theoretical formulas gave results ranging from about 850 second-feet too small at low stages, with the sluices closed, to 250 second-feet too large at high stages, with all sluices open. The deficiency of amounts in the old records as published is due to the fact no allowance was made for leakage through the dam, which is now determined to be about 1,000 second-feet with water at the crest of the dam and all gates closed. Discharge measurements made by the United States Geological Survey in 1902 and 1903 at Wrightstown, about 2 miles below the dam, indicate that the leakage at the dam was apparently the same during 1902 and 1903 as at the present time. As Rapide Croche dam was built in 1878 and existed in 1902 as in 1917, it is considered necessary and proper to correct the old records for 1896–1917 to agree with the results of the current-meter measurements of 1917. The records published herewith are the old records corrected by means of the curves for 1917, each recomputation taking into consideration the relation between the old and new curves according to the number of sluice gates open. Corrections were applied to the semimonthly and monthly mean discharge. The yearly discharge is derived from the mean monthly discharge. The semimonthly and mean monthly discharge was computed by engineers of the office of the Army Engineer Corps at Milwaukee; the flow in second-feet per square mile, run-off depth in inches, and yearly means and totals were computed by engineers of the United States Geological Survey.

EXTREMES OF DISCHARGE.—Not determined. Information regarding the daily maximum and minimum may be obtained from the office of the Corps of Engineers, United States Army, Milwaukee, Wis.

REGULATION.—Flow regulated by Lake Winnebago, which has an area of 215 square miles, and also by dams between the outlet of Lake Winnebago and the station, the dams being operated for power development and to some extent in the interests of navigation. Under existing conditions, which, as regards storage, have been the same throughout the period covered by the records, the flow past the station is natural.

ACCURACY.—Though the accuracy of the records prior to 1902–1903 is somewhat doubtful it is believed that the records for entire period are good. See "Determination of discharge."

COOPERATION.—Records collected and monthly and semimonthly discharge computed by the United States Army Engineers from curves based on current-meter measurements made by engineers of the United States Geological Survey.

Discharge of Fox River at Rapide Croche dam, Wis., for years ending Sept. 30, 1896–1917.

NOTE.—Records in the above table supersede those contained in the "Water-power report to the Legislature, 1915," published by the Wisconsin Railroad Commission.

WOLF RIVER AT KESHENA, WIS.

LOCATION.—In sec. 26, T. 28 N., R. 15 E., at the highway bridge at Keshena, Shawano County, 3 miles below the junction with West Branch of Wolf River, which enters from the right.

DRAINAGE AREA.—797 square miles.

RECORDS AVAILABLE.—May 9, 1907, to March 31, 1909; February 10, 1911, to September 30, 1917.

GAGE.—Chain gage fastened to downstream side of new bridge on December 9, 1914; May 9, 1907, to November 29, 1914, vertical staff gage fastened to downstream abutment, both gages at same datum; read by Jerome M. Beauprey.

DISCHARGE MEASUREMENTS.—Made from the bridge.

CHANNEL AND CONTROL.—Gravel; smooth and practically permanent. Banks of mediun height; overflow improbable. During the last part of November and the first part of December, 1914, a new bridge was erected at the site of the old gage. The plotting of the discharge measurements made since the bridge was built indicates that the construction of the new piers changed condition of channel.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 4.50 feet at 5 p. m. June 8 and 8 a. m. June 9 (discharge, 2,260 second-feet); minimum discharge about 470 second-feet February 18.

1907–1909 and 1911–1917: Maximum discharge recorded 3,910 second-feet September 2, 1912; minimum open-water discharge, 275 second-feet September 26, 1908.

ICE.—Stage-discharge relation seriously affected by ice.

REGULATION.—The river and its main tributaries above Keshena are controlled to some extent by logging dams.

ACCURACY.—Stage-discharge relation permanent except as affected by ice. Rating curve well defined between 510 and 2,260 second-feet; above and below these limits curve is extended and is subject to error. Gage read to quarter-tenths twice daily. Daily discharge ascertained by applying mean of daily gage heights to rating table, except for period when stage-discharge relation was affected by ice, for which it was ascertained by applying to rating curve mean daily gage height corrected for effect of ice by means of discharge measurements, observer's notes, and weather records. Open-water records excellent except for extremely high and low stages, for which they are fair; winter records fair.

Discharge measurements of Wolf River at Keshena, Wis., during the year ending September 30, 1917.

WOLF RIVER AT NEW LONDON, WIS.

Location.—In sec. 12, T. 22 N., R. 14 E., at Pearl Street highway bridge, New London Waupaca County. Embarrass River enters from the right three-fourths of a mile above the station, and Little Wolf River, also from the right, 5 miles below.

Drainage area.—2,240 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale, 1 inch = 6 miles).

Records available.—Gage heights March 1, 1899, to September 30, 1917; daily discharge record, October 1, 1913, to September 30, 1917.

Gage.—Enameled steel gage, reading from 1.0 to 13.0 feet, fastened to right-hand downstream pier of Pearl Street bridge. Datum of the gage raised 0.641 foot March 1, 1911, according to the United States Army Engineers. Zero of gage 748.874 feet above mean sea level, New York City datum.

Discharge measurements.—Made from the Shawano Street bridge, two blocks below the gage.

Channel and control.—Bed composed of sand, hardpan, and mud; not permanent. No well-defined control. Banks at gage fairly high and not subject to overflow. It is reported that during extremely high stages water from Embarrass River flows across New London into the channel of Wolf River below the gage.

Extremes of discharge.—Maximum stage recorded during the year, 9.45 feet April 1 (discharge, 8,060 second-feet); minimum discharge about 840 second-feet February 8–12.

1914–1917: Maximum discharge recorded, 8,960 second-feet April 4, 1916; minimum discharge, 755 second-feet January 1–10, 1915. The United States Army Engineer Office reports a stage of 11.6 feet April 16, 1888.

Ice.—Stage-discharge relation affected by ice.

Regulation.—Little if any diurnal fluctuation due to operation of the power plants on river above station observable at gage; monthly flow natural.

Accuracy.—Stage-discharge relation not permanent. Two rating curves used during 1917; one applicable October 1 to March 31 fairly well defined between 910 and 9,280 second-feet; the other, applicable April 1 to September 30, fairly well defined between 1,080 and 9,280 second-feet. Gage read to tenths once daily. Daily discharge ascertained by applying daily gage height to rating table, except for period when stage-discharge relation was affected by ice, for which it was obtained by applying to rating table daily gage height corrected for effect of ice by means of discharge measurements, observer's notes, and weather records. Records fair.

Discharge measurements of Wolf River at New London, Wis., during the year ending Sept. 30, 1917.

WEST BRANCH OF WOLF RIVER AT NEOPIT, WIS.

LOCATION.—In sec. 20, T. 29 N., R. 14 E., at dam and power plant at Neopit, Shawano County, a station on Wisconsin Northern Railroad, 20 miles north of Shawano; about 11 miles above confluence of Wolf River and West Branch.

DRAINAGE AREA.—108 square miles.

RECORDS AVAILABLE.—January 25, 1911, to February 7, 1917, when station was discontinued.

GAGE.—Vertical staff, head and tail race gages.

DETERMINATION OF FLOW.—Observations of the head of water flowing over the spillway, the head on the wheels, and the kilowatt output as measured at the switchboard are taken at 6, 7, and 10 a. m. and at 3, 6, and 10 p. m. The flow at these times is determined by means of a curve developed by current-meter measurements, and the computed discharge is then weighted in accordance with the elapsed interval.

EXTREMES OF DISCHARGE.—Maximum daily discharge recorded during year, 169 second-feet, January 7; minimum daily discharge, 62 second-feet December 10.

1911–1917: Maximum daily discharge, 999 second-feet, July 24, 1912; minimum daily discharge, 17 second-feet, August 30, 1914. Extremes are caused by regulation, and are not natural.

ACCURACY.—Rating tables used in determination of daily discharge based on numerous measurements made throughout the year. Conditions relative to leakage and plant equipment are becoming more unsatisfactory; records published for year only fair.

Daily discharge, in second-feet, of West Branch of Wolf River at Neopit, Wis., for the period Oct. 1, 1916, to Feb. 7, 1917.

LITTLE WOLF RIVER AT ROYALTON, WIS.

LOCATION.—In sec. 1, T. 22 N., R. 13 E., at highway bridge at Royalton, Waupaca County, about 4 miles above mouth of river.

DRAINAGE AREA.—485 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

RECORDS AVAILABLE.—January 13, 1914, to September 30, 1917.

GAGE.—Sloping gage on left bank 150 feet upstream from highway bridge; read by J. C. Jenson. Prior to August 21, 1915, a chain gage fastened to upstream side of highway bridge was used. Datum of sloping gage is 0.75 foot higher than that of the chain gage; owing to change in slope, however, difference between readings on the slope gage and the chain gage is not constant.

DISCHARGE MEASUREMENTS.—Made by wading or from cable about 500 feet upstream from chain gage.

CHANNEL AND CONTROL.—Stream bed at gage consists of heavy gravel and rock; fairly permanent; at measuring section bed is fine, smooth gravel. Neither bank is overflowed to any extent at flood stages.

EXTREMES OF DISCHARGE.—Maximum discharge recorded during year, about 4,800 second-feet March 26; minimum discharge recorded, about 130 second-feet January 23.

1914–1917: Maximum stage recorded, 7.5 feet at 7.15 p. m., June 7, 1914 (discharge, 5,350 second-feet); a higher stage was recorded in March, 1917, but discharge was less owing to backwater from ice; minimum discharge recorded, about 130 second-feet March 5 and 6, 1916, and January 23, 1917.

ICE.—Stage-discharge relation affected by ice.

REGULATION.—The few power plants above the station have little storage and produce no observable diurnal fluctuation at the gage.

ACCURACY.—Stage-discharge relation not permanent. Two rating curves used during the year; one applicable for periods when slope gage was read—October 1 to November 15, November 21–24, December 1–6, and June 19 to September 30—well defined between 209 and 1,570 second-feet; the other, applicable to chain-gage readings, poorly defined throughout. Gage read to quarter-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table, except for period when stage-discharge relation was affected by ice, for which it was obtained by applying to rating table mean daily gage height corrected for effect of ice by means of discharge measurements, observer's notes, and weather records. Open-water records good except for high stages, for which they are fair; winter records fair.

Discharge measurements of Little Wolf River at Royalton, Wis., during the year ending Sept. 30, 1917.

WAUPACA RIVER NEAR WEYAUWEGA, WIS.

Location.—On line between sec. 1, T. 21 N., R. 12 E., and sec. 6, T. 21 N., R. 13 E., at highway bridge 2½ miles west of Weyauwega, Waupaca County.

Drainage area.—308 square miles (measured on Wisconsin Geological and Natural History Survey map, edition of 1911; scale 1 inch=6 miles).

Records available.—June 28, 1916, to October 18, 1917, when station was moved one mile upstream.

Gage.—Chain gage bolted to top chord, downstream truss, across left channel; read by Otto Reek and Harry Radtke.

Discharge measurements.—Made from downstream side of bridge or by wading about 300 feet above bridge.

Channel and control.—Bed composed of coarse gravel; clean and free from aquatic grass. Control is a fairly well defined riffle about 30 feet downstream from gage. Right bank high, wooded, and will be overflowed only occasionally; left bank low and subject to overflow; road is high, so that during ordinary flood stages all the water passes under the bridge.

Ice.—Stage-discharge relation affected by ice.

Extremes of discharge.—Maximum stage recorded during period of records 6.1 feet March 23, 1917; owing to ice effect maximum discharge occurred about March 25, and has been estimated at 920 second-feet. Minimum discharge about 130 second-feet, February 13, 1917.

Regulation.—Several power plants at Waupaca and above on the main stream and also several on the Crystal River cause slight fluctuations during low stages. The pondage at the various plants is small; mean monthly discharge is believed to represent nearly the natural flow.

Accuracy.—Stage-discharge relation assumed practically permanent. Rating curve based on 7 current-meter measurements made in 1916 and 1917 and 4 measurements made in 1918 at the new site 1 mile upstream; curve fairly well defined between 158 and 448 second-feet; above 448 second-feet rating curve is an extension and subject to possible error. Gage read to hundredths once daily. Daily discharge ascertained by applying daily gage height to the rating table; except for periods when the stage-discharge relation was affected by ice, for which it was obtained by applying to rating table gage height corrected for ice effect by means of discharge measurements, observer's notes, and weather records. Records probably not better than fair for entire period.

Discharge measurements of Waupaca River near Weyauwega, Wis., during the period Oct. 1, 1916, to Oct. 26, 1917.

SHEBOYGAN RIVER NEAR SHEBOYGAN, WIS.

LOCATION.—In sec. 28, T. 15 N., R. 23 E., 2 miles west of Sheboygan, Sheboygan County, and 2½ miles above mouth.

DRAINAGE AREA —403 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale, 1 inch=6 miles.

RECORDS AVAILABLE.—June 30, 1916, to September 30, 1917.

GAGE.—Chain gage fastened to upstream side of bridge; read by Hattie Opgenorth.

DISCHARGE MEASUREMENTS.—Made from highway bridge, or by wading; at extreme flood stages, measurements are made from Chicago & North Western Railway bridge, one-third mile downstream.

CHANNEL AND CONTROL.—Control, well defined riffle about 200 feet below bridge. Stream bed composed of heavy gravel; clear and free from aquatic grass. Both banks are of medium height and are rarely overflowed.

EXTREMES OF DISCHARGE.—1916-17: Maximum discharge 1,490 second-feet March 22 to 24; minimum stage recorded, 1.84 feet at 6.30 p. m., September 2, 1916 (discharge, 16 second-feet).

ICE.—Stage-discharge relation affected by ice.

REGULATION.—At low stages there is a small amount of diurnal fluctuation due to operation of small power plants above.

ACCURACY.—Stage-discharge relation permanent, except when affected by ice. Rating curve well defined between 58 and 1,040 second-feet, poorly defined outside these limits. Gage read to quarter-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table, except for periods when stage-discharge relation was affected by ice, for which it was obtained by applying to rating curve mean daily gage height corrected for effect of ice by means of discharge measurements, observers' notes, and weather records. Open-water records excellent; winter records fair.

Discharge measurements of Sheboygan River near Sheboygan, Wis., during year ending Sept. 30, 1917.

MILWAUKEE RIVER NEAR MILWAUKEE, WIS.

Location.—In NW. ¼ sec. 5, T. 7 N., R. 22 E., immediately above an old quarry near north limits of Milwaukee, Milwaukee County, about half mile below concrete highway bridge and 1 mile above Mineral Spring road; 5½ miles above confluence of Milwaukee and Menominee rivers.

Drainage area.—661 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

Records available.—April 30, 1914, to September 30, 1917.

Gage.—Chain gage fastened to cantilever arm supported by posts set in concrete foundations on the left bank of the river; read by Mrs. Joe Wangard.

Channel and control.—Bed of channel at gage heavy gravel. About 200 feet below the gage is a rock outcrop with a 4-foot fall which forms the control, and is probably permanent. Below the control the river flows in an artificial channel which at one time was a quarry. Left bank above and below the control high and not subject to overflow; right bank above control of medium height; below the control the right bank is artificial and of such height that overflow will rarely occur.

Discharge measurements.—Made by wading immediately above the gage section; at medium and high stages from the lower members of a wooden railroad bridge about 700 feet below the gage; bridge crosses an abandoned quarry and the channel beneath, being artificial, affords an excellent measuring section. During the summer of 1917 the bridge burned down and at present there is no suitable point for high-water measurements.

Extremes of discharge.—Maximum stage recorded during year 5.5 feet at 5 p.m. March 25 (discharge, about 5,160 second-feet); minimum stage recorded 0.62 foot at 5.30 a. m. September 2 (discharge 48 second-feet).

1914–1917: Maximum stage recorded 5.58 feet February 24, 1915 (discharge 5,280 second-feet); minimum stage recorded 0.50 foot at 8.30 p. m. August 2, 1916 (discharge, about 26 second-feet).

Ice.—Stage-discharge relation affected by ice.

REGULATION.—No diurnal fluctuation at the gage resulting from operation of small plants above.

ACCURACY.—Stage-discharge relation practically permanent except as affected by ice. Rating curve well defined between 88 and 3,710 second-feet; poorly defined outside these limits. Gage read to quarter-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table, except for period when stage-discharge relation was affected by ice, for which it was obtained by applying to rating table mean of daily gage height corrected for effect of ice by means of discharge measurements, observer's notes, and weather records. Open-water records excellent, except for extreme high and low stages, for which they are only fair; winter records fair.

Discharge measurements of Milwaukee River near Milwaukee, Wis., during the year ending Sept. 30, 1917.

LITTLE CALUMET RIVER AT HARVEY, ILL.

LOCATION.—In NW. ¼ sec. 9, T. 36 N., R. 14 E., at Illinois Central Railroad bridge 800 feet north of railroad station at 147th Street, Harvey, Cook County, about 11 miles above mouth of river.

DRAINAGE AREA.—570 square miles (measured on map issued by U. S. Geological Survey, scale 1:500,000).

RECORDS AVAILABLE.—Daily discharge, October 1, 1916, to September 30, 1917; also daily gage-height record collected by Sanitary District of Chicago, June 10, 1907, to September 30, 1916.

GAGE.—Vertical staff gage attached to bridge pier; read by Mrs. H. Wurtman.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge or by wading.

CHANNEL AND CONTROL.—Bed of river composed of clay and gravel. Low-water control is at "The Rocks," about a mile below gage; bed of river heavy gravel; probably permanent. Banks not subject to overflow.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 6.1 feet March 14 (discharge, 1,120 second-feet); minimum stage, 2.96 feet at 5 p. m. August 27 (discharge, 48 second-feet).

1910-1917: Maximum stage recorded, 13.4 feet March 6, 1908 (discharge not determined); minimum stage, 2.9 feet August 10, 1916 (discharge, 39 second-feet).

ACCURACY.—Stage-discharge relation probably permanent throughout the year; seriously affected by ice during the winter. Rating curve well defined above and fairly well defined below 70 second-feet. Gage read to tenths three times daily October 1 to June 1, and to hundredths twice daily June 2 to September 30. Daily discharge ascertained by applying mean daily gage height to rating table. Open-water records good; winter records poor.

COOPERATION.—Gage-height records from October 1 to June 1 furnished by the Sanitary District of Chicago.

Discharge measurements of Little Calumet River at Harvey, Ill., during the year ending Sept. 30, 1917.

GRAND RIVER AT GRAND RAPIDS, MICH.

LOCATION.—At Fulton Street Bridge, Grand Rapids.

DRAINAGE AREA.—4,900 square miles.

RECORDS AVAILABLE.—March 12, 1901, to September 30, 1917.

GAGE.—Staff, attached to bridge; read to half tenths October 1, 1916 to February 10, 1917, and to tenths after February 10, 1917; twice daily October 1 to January 5 and March 12 to May 26; once daily during remainder of year.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge.

EXTREMES OF STAGE.—Maximum stage recorded during year 8.8 feet at 5 p. m. April 10; minimum stage recorded, −1.5 feet, about 2 weeks in August.

ICE.—Stage-discharge relation somewhat affected by ice.

REGULATION.—Operation of power plants above station may modify low-water flow.

ACCURACY.—The two or three measurements made since 1905 indicate that the rating curve used in 1905 was not applicable after that year.

COOPERATION.—Records furnished by city engineer of Grand Rapids.

No discharge measurements made during the year.

Daily gage height, in feet, of Grand River at Grand Rapids, Mich., for the year ending Sept. 30, 1917.

NOTE.—Gage read to top of ice, Jan. 15, 16, 22, Feb. 5, 15 and 16. Gage heights, Dec. 17-31, Jan. 8-13, 23, 24 and 29, estimated by observer owing to ice.

STREAMS TRIBUTARY TO LAKE HURON.

TITTABAWASSEE RIVER AT FREELAND, MICH.

LOCATION.—At Highway bridge at Freeland.

DRAINAGE AREA.—2,530 square miles.

RECORDS AVAILABLE.—August 22, 1903, to August 3, 1906; October 28, 1906, to December 31, 1909; January 1, 1912, to September 30, 1917.

COOPERATION.—Estimates of daily discharge were made and furnished by G. S. Williams, consulting engineer, Ann Arbor, Mich.

Daily discharge, in second-feet, of Tittabawassee River at Freeland, Mich., for the year ending Sept. 30, 1917.

Day.	Oct.	Nov.	Dec.	Jan.	Feb.	Mar.	Apr.	May.	June.	July.	Aug.	Sept.
1	1,140	1,300	1,745	1,119	1,201	1,256	3,760	4,770	1,905	3,760	730	930

NOTE.—Monthly and yearly discharge computed by engineers of the United States Geological Survey.

STREAMS TRIBUTARY TO LAKE ERIE.

HURON RIVER AT BARTON, MICH.

Location.—At dam and power plant of the Eastern Michigan Edison Co. at Barton, near Ann Arbor, 4 miles above the station at Geddes.

Drainage area.—723 square miles.

Record available.—January 1, 1914, to September 30, 1917.

Determination of discharge.—Flow computed from records of operation of power plant, the flow through under-sluices during floods, and the depth of flow over dam. The flow through the power house is determined from a calibration of the turbines by means of a specially constructed weir, the crest of which was formed by a ½-inch by 5-inch milled plate, the discharge over the weir being computed by Bazin's formula for free overflow. The greater part of the flood water passes through under-sluices in the power-house foundations, and this flow is determined from a weir calibration of the sluices. Water flows over crest of dam only a few days during the year.

Cooperation.—Daily-discharge record furnished by G. S. Williams, consulting engineer, Ann Arbor, Mich.

Daily discharge, in second-feet, of Huron River at Barton, Mich., for the year ending Sept. 30, 1917.

NOTE.—Monthly and yearly discharge computed by engineers of the United States Geological Survey.

HURON RIVER AT FLAT ROCK, MICH.

LOCATION.—At the highway bridge at Flat Rock, 2,000 feet below the crossing of Detroit, Toledo & Ironton Railway.

DRAINAGE AREA.—1,000 square miles.

RECORDS AVAILABLE.—August 6, 1904, to September 30, 1917.

GAGE.—Staff; read daily, morning and evening, to tenths, by C. L. Metler.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge.

CHANNEL AND CONTROL.—Probably permanent.

EXTREMES OF STAGE.—Maximum stage recorded during year, 7.6 feet, at 5.30 p. m., April 7; minimum stage recorded, 1.0 foot, September 25 and 29.

ICE.—Ice jams form below the station and cause backwater at the gage; in general the section above the station is kept open by the power plant.

REGULATION.—At ordinary stages flow of the river is controlled by a dam and power plant immediately above station, but operation of this plant is assumed to have little effect on diurnal fluctuations of stage.

No discharge measurements were made at this station during the year.

Daily gage height, in feet, of Huron River at Flat Rock, Mich., for the year ending Sept. 30, 1917.

CATTARAUGUS CREEK AT VERSAILLES, N. Y.

Location.—At the three-span highway bridge in Versailles, Cattaraugus County, 2½ miles above mouth of Clear Creek, about 6 miles below Gowanda, and about 8 miles above mouth of stream.

Drainage area.—467 square miles (measured on post-route map).

Records available.—September 23, 1910, to September 30, 1917.

Gage.—Chain on upstream side of right span of bridge; read by James Palmer.

Discharge measurements.—Made from downstream side of bridge or by wading.

Channel and control.—Bed composed of rock and gravel; shifting.

Extremes of discharge.—Maximum stage recorded during year, 8.2 feet at 9 a. m. March 17 (discharge, about 8,460 second-feet); minimum stage recorded, 4.45 feet October 7, 8, and 11 (discharge, 64 second-feet).

1910–1917: Maximum stage recorded, 11.6 feet at 5.40 p. m. March 25, 1913 (discharge, roughly 30,000 second-feet); minimum stage recorded, 4.65 feet August 21 and September 6, 7, 1913 (discharge, 55 second-feet).

Ice.—Stage-discharge relation seriously affected by ice.

Accuracy.—Stage-discharge relation not permanent; affected by ice during much of the period December to March, inclusive. Gage read to half-tenths twice daily. Daily discharge throughout year ascertained by indirect method, applying mean daily effective gage height to rating table; corrections for obtaining effective gage heights determined from discharge measurements. Records fair.

Discharge measurements of Cattaraugus Creek at Versailles, N. Y., during the year ending Sept. 30, 1917.

NOTE.—Discharge, Dec. 13–27 and Jan. 15 to Feb. 26, estimated because of ice from discharge measurements, weather records, study of gage-height graph and comparison with records for stations on streams in adjacent drainage basins.

Monthly discharge of Cattaraugus Creek at Versailles, N. Y., for the year ending Sept. 30, 1917.

[Drainage area, 467 square miles.]

STREAMS TRIBUTARY TO LAKE ONTARIO.

LITTLE TONAWANDA CREEK AT LINDEN, N. Y.

Location.—At stone-arch highway bridge in Linden, Genesee County, 3 miles above junction with Towanda Creek.

Drainage area.—22.0 square miles (measured on topographic maps).

Records available.—July 8, 1912, to September 30, 1917.

Gage.—Vertical staff on upstream side of right abutment; lower 2 feet of enameled iron, graduated to hundredths of a foot; upper 4 feet of bronze, graduated to half-tenths; read by C. L. Schenck.

Discharge measurements.—Made from cable 1,000 feet above gage or by wading near gage.

Channel and control.—A standard Francis weir, 2.01 feet long and 8 inches high, has been constructed under the upstream side of the bridge. When the water overtops this weir it flows over a 2-inch plank about 13 feet long, including the 2 feet of weir. During the winter of 1916–17 crest of weir was worn down by ice passing over it and it was necessary to develop a new rating curve. A tree that lodged against the weir June 26 was partly removed June 28 and entirely removed July 14. Crest of weir was repaired August 20.

Extremes of discharge.—Maximum stage during year, from water marks on gage, 9.5 feet in early morning of June 27 (discharge not computed); minimum stage recorded, 0.20 foot October 8 and 9 (discharge, 0.51 second-foot).

1912–1917: Maximum stage, determined by leveling from flood marks, 14.6 feet during flood of April 22, 1916 (discharge, about 2,400 second-feet); minimum stage recorded, 0.18 foot August 20 and 21, September 14–16, and October 8, 1913 (discharge, 0.43 second-foot).

Accuracy.—Stage-discharge relation permanent except for changes caused by wearing of crest of weir by ice. Rating curve used October 1 to March 11 and August 21 to September 30, when weir was in good condition, well defined below 250 second-feet and fairly well defined between 250 and 750 second-feet; curves for period during which weir was obstructed by tree or when crest was in damaged condition are fairly well defined. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records good for period when weir was in good condition; fair for rest of year.

Discharge measurements of Little Tonawanda Creek at Linden, N. Y., during the year ending Sept. 30, 1917.

GENESEE RIVER AT SCIO, N. Y.

Location.—At steel highway bridge one-fourth mile above Vandermark Creek, half a mile above Scio, Allegany County, and 1 mile above Knight Creek.

Drainage area.—297 miles (measured on map issued by United States Geological Survey, scale, 1:500,000).

Records available.—June 12, 1916, to September 30, 1917.

Gage.—Vertical staff attached to downstream face of left bridge abutment; read by Raymond Sisson.

Discharge measurements.—Made from downstream side of bridge or by wading.

Channel and control.—Coarse gravel; probably permanent.

Extremes of discharge.—Maximum stage recorded during year, 5.1 feet July 2 (discharge, 3,710 second-feet); minimum discharge recorded, 26 second-feet February 13.

1916–17: Maximum stage recorded, 8.7 feet at 8 a. m. June 17, 1916 (discharge, about 9,800 second-feet); minimum stage recorded, 0.60 foot August 25, 26, 1916 (discharge, 25 second-feet).

Ice.—Stage-discharge relation affected by ice.

Accuracy.—Stage-discharge relation practically permanent; affected by ice during much of period December to March. Rating curve well defined between 25 and 5,500 second-feet. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Open-water records good; winter records fair.

Discharge measurements of Genesee River at Scio, N. Y., during the year ending Sept. 30, 1917.

GENESEE RIVER AT ST. HELENA, N. Y.

Location.—At steel highway bridge in St. Helena, Wyoming County, 5½ miles below Portageville and site of proposed storage dam of New York Conservation Commission and 9½ miles above mouth of Canaseraga Creek.

Drainage area.—1,030 square miles.

Records available.—August 14, 1908, to September 30, 1917.

Gage.—Gurley seven-day water-stage recorder, installed July 22, 1916. Prior to that date a chain gage fastened to upstream side of bridge, middle span, installed August 14, 1908, and a Gurley printing water-stage recorder, installed August 24, 1911. Water-stage recorder inspected and chain gage read by Herman Piper.

Discharge measurements.—Made from bridge or by wading.

Channel and control.—Gravel and rocks; shifting occasionally.

Extremes of discharge.—Maximum stage during year, from water-stage recorder, 8.70 feet at 11 a. m. March 12 (discharge, 16,700 second-feet); minimum stage, from water-stage recorder, 1.80 feet at 1 a. m. October 2 (discharge, 50 second-feet).

1908–1917: Maximum stage, from water-stage recorder, 12.81 feet at 8 a. m. May 17, 1916 (discharge, 43,500 second-feet); minimum stage recorded, 1.70 feet at 5 p. m. October 5 and 8 a. m. October 17, 1913 (discharge, about 18 second-feet).

Ice.—Stage-discharge relation somewhat affected by ice.

Accuracy.—Stage-discharge relation not permanent. Rating curve for water-stage recorder, used October 1 to March 12 and September 17–30, well defined between 75 and 2,000 second-feet and fairly well defined between 2,000 and 30,000 second-feet; rating curve for chain gage, used March 12 to September 16, well defined between 500 and 1,600 second-feet. Gage read to quarter-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table except for days of great range in stage, when it was determined by averaging results obtained by applying to rating table gage heights for 2-hour periods. Records good.

Discharge measurements of Genesee River at St. Helena, N. Y., during the year ending Sept. 30, 1917.

GENESEE RIVER AT JONES BRIDGE, NEAR MOUNT MORRIS, N. Y.

LOCATION.—At highway bridge known as Jones Bridge, 1½ miles below Canaseraga Creek, 1½ miles above mouth of Beads Creek, 5 miles below Mount Morris, Livingston County, and 6 miles by river above Geneseo.

DRAINAGE AREA.—1,410 square miles.

RECORDS AVAILABLE.—May 22, 1903, to April 30, 1906; August 12, 1908, to December 31, 1913; July 12, 1915, to September 30, 1917.

GAGE.—Gurley seven-day water-stage recorder installed September 11, 1915, on right bank 60 feet downstream from bridge. Prior to 1915 a chain gage fastened to upstream side of highway bridge was used. Datum of water-stage recorder, 2.73 feet higher than that of chain gage (540.00 feet Conservation Commission datum). Recorder inspected by Theron S. Trewer.

DISCHARGE MEASUREMENTS.—Made from footbridge erected on lower chord of upstream bridge truss.

CHANNEL AND CONTROL.—Sandy clay; likely to shift but, as shown by discharge measurements, fairly permanent in recent years.

EXTREMES OF DISCHARGE.—Maximum stage during year, from water-stage recorder, 23.5 feet at 2.30 p. m. March 12 (discharge, 31,800 second-feet); minimum stage, from water-stage recorder, 0.63 foot at 6 p. m. October 2 (discharge, 92 second-feet).

1902–1917: Maximum stage recorded, 25.44 feet at noon May 17, 1916 (discharge, 55,100 second-feet); minimum stage recorded, 2.7 feet at 6 p. m. August 29, 1909 (discharge, about 18 second-feet). See paragraph headed "Records available" for limits of periods of no records.

ICE.—Stage-discharge relation affected by ice.

REGULATION.—Some diurnal fluctuation due to operation of mills at Mount Morris is observable during extremely low water.

ACCURACY.—Stage-discharge relation practically permanent between dates of shifting; affected by ice for much of January, February, and March. Rating curve well defined between 150 and 7,000 second-feet and fairly well defined between 7,000 and 60,000 second-feet. Operation of water-stage recorder satisfactory throughout year. Daily discharge ascertained by applying to rating table mean daily gage height obtained by inspecting recorder graph or, for days of considerable fluctuation, by discharge integrator.

Discharge measurements of Genesee River at Jones Bridge, near Mount Morris, N. Y., during the year ending Sept. 30, 1917.

GENESEE RIVER AT ROCHESTER, N. Y.

LOCATION.—At Elmwood Avenue Bridge at north end of South Park, 3¼ miles below mouth of Black Creek, 3½ miles above center of city of Rochester, Monroe County, and 7½ miles above mouth of river.

DRAINAGE AREA.—2,360 square miles.

RECORDS AVAILABLE.—February 9, 1904, to September 30, 1917. Fragmentary records prior to this period published in Water-Supply Papers 24, 65 and 97.

GAGE.—Gurley water-stage recorder installed in December, 1910, in the pump house on right bank, immediately below the bridge. Recorder inspected by George A. Bailey. Prior to December, 1910, a staff gage bolted to downsteam end of first pier from right abutment. Elevation of zero of gage, 506.848 feet, Barge Canal datum, and 245.591 feet, Rochester City datum.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge. Prior to 1904 measurements and elevation of water surface taken in conjunction with the city of Rochester.

CHANNEL AND CONTROL.—Smooth gravel; apparently permanent.

EXTREMES OF DISCHARGE.—Maximum stage during year, from water-stage recorder, 7.38 feet at 7 p. m. March 14 (discharge, 14,200 second feet); minimum stage, from water stage recorder, 0.95 foot at 12 p. m. October 9 (discharge, 214 second-feet.)

1904–1917: Maximum stage, from water-stage recorder, 15.3 feet at midnight March 30, 1916 (discharge, 48,300 second-feet); minimum stage from water-stage recorder, 0.71 foot from 10 p. m. September 30 to 4 a. m. October 1, 1913 (discharge, 154 second-feet.

ICE.—Stage-discharge relation affected by ice during a large part of the period from December to March.

ACCURACY.—Stage-discharge relation practically permanent except as affected by ice. Rating curve well defined between 2,000 and 44,000 second-feet. Operation of water-stage recorder satisfactory throughout year. Daily discharge ascertained by applying to rating table mean daily gage height obtained by averaging hourly gage heights. Open-water records good; other records fair.

COOPERATION.—Water-stage recorder inspected by an employee of the Rochester Railway & Light Co.

Discharge measurements of Genesee River at Rochester, N. Y., during the year ending Sept. 30, 1917.

CANASERAGA CREEK NEAR DANSVILLE, N. Y.

Location.—At highway bridge 1 mile west of Dansville, Livingston County, 2,200 feet below mouth of Mill Brook and about 22 miles above mouth of creek.

Drainage area.—167 square miles (measured by engineers of the State of New York Conservation Commission).

Records available.—July 21, 1910, to December 31, 1912; July 10, 1915, to June 30, 1917, when station was discontinued.

Gage.—Vertical staff at downstream side of left abutment; datum lowered 4.77 feet (to Conservation Commission datum, 640.00 feet) July 10, 1915. Gage read by Floyd Harter.

Discharge measurements.—Made from bridge or by wading.

Channel and control.—Sand and gravel; shifting frequently.

Extremes of discharge.—Maximum stage recorded during year, 9.3 feet at 7 a. m. June 11 (discharge, about 2,380 second-feet); minimum stage recorded, 5.2 feet several times during October and November (discharge, about 15 second-feet).

1910–1912 and 1915–1917: Maximum stage recorded, 13.0 feet at 9.30 p. m. May 16, 1916 (discharge, determined from logarithmic extension of rating curve roughly, 6,600 second-feet); minimum stage recorded, 5.2 feet several times during October and November, 1916.

Ice.—Stage-discharge relation affected by ice; observations of stage discontinued during winter.

Accuracy.—Stage-discharge relation not permanent; frequent discharge measurements necessary for determination of discharge; affected by ice December to March. Rating curve not well defined. Gage read to half tenths twice daily. Daily discharge October 1 to December 12 ascertained by applying daily gage height to rating table; March 1 to June 30, by shifting-control method. Records fair.

Discharge measurements of Canaseraga Creek near Dansville, N. Y., during the year ending Sept. 30, 1917.

CANASERAGA CREEK AT GROVELAND STATION, N. Y.

LOCATION.—At highway bridge at Groveland Station, Livingston County.

DRAINAGE AREA.—195 square miles (measured by engineers of State of New York Conservation Commission.)

RECORDS AVAILABLE.—August 5, 1915, to September 30, 1916; February 28 to September 30, 1917.

GAGE.—Chain gage near center of downstream side of bridge. Prior to March 30, 1916, inclined staff on right bank about 400 feet above bridge, at practically same datum (560.00 feet, Conservation Commission datum). Gage read by L. J. Dagon and Thomas Maimone.

DISCHARGE MEASUREMENTS.—Made from highway bridge or by wading.

CHANNEL AND CONTROL.—Creek flows through improved channel which is in gravel and is likely to shift.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 16.5 feet from 2 to 3 p. m. July 29 (discharge, 4,170 second-feet); minimum stage recorded, 6.7 feet at 6 p. m. August 20 and 8 a. m. and 6 p. m. August 26, 27 (discharge, 47 second-feet).

1915–1917: Maximum stage recorded July 29, 1917; minimum stage recorded, 6.5 feet from 6 p. m. September 21 to 6 p. m. September 22, 1916 (discharge 36 second-feet).

ICE.—Stage-discharge relation affected by ice. Observations of stage suspended during winter.

ACCURACY.—Stage-discharge relation permanent; affected by ice December to March. Rating curve well defined between 35 and 3,000 second-feet. Gage read by half-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records good except those for floods of several days' duration, when stage-discharge relation may be affected by backwater.

Discharge measurements of Canaseraga Creek at Groveland Station, N. Y., during the year ending Sept. 30, 1917.

CANASERAGA CREEK AT SHAKERS CROSSING, N. Y.

LOCATION.—At highway bridge at Shakers Crossing, about a mile above mouth, and 1¼ miles northeast of Mount Morris, Livingston County.

DRAINAGE AREA.—347 square miles (measured by engineers of New York State Conservation Commission).

RECORDS AVAILABLE.—Occasional current-meter measurements 1904–1915: continuous record of gage height and occasional current-meter measurements July 13, 1915, to September 30, 1917.

GAGE.—Gurley seven-day water-stage recorder on the left bank, just below bridge. Datum of gage same as that established on Genesee River at Jones Bridge near Mount Morris July 12, 1915 (540.00 feet Conservation Commission datum). Recorder inspected [illegible] Russell.

Discharge measurements.—Made from the highway bridge or by wading.

Channel and control.—Firm gravel; not likely to shift; subject to backwater from Genesee River.

Ice.—Stage-discharge relation affected by ice.

Extremes of stage.—Maximum stage during year, from water-stage recorder, 25.10 feet at 4 p. m. March 12; minimum stage, from water-stage recorder, 7.95 feet at 11 p. m. October 30.

1915–1917: Maximum stage, from water-stage recorder, 28.92 feet at 1 p. m. May 17, 1916; minimum stage, from water-stage recorder, 7.95 feet at 11 p. m. October 30, 1916.

Data on extent and duration of backwater from Genesee River too meager to permit accurate determination of discharge.

Discharge measurements of Canaseraga Creek at Shakers Crossing, N. Y., during the year ending Sept. 30, 1917.

Note.—Intake to float well stopped by silt June 28 to July 1, July 4–10, and July 31 to August 22. Gage heights for following periods are mean of two observations per day on staff gage: July 8–10 and July 31 to Aug. 22.

KESHEQUA CREEK NEAR SONYEA, N. Y.

Location.—About 400 feet above Delaware, Lackawanna & Western Railroad bridge and half a mile below gaging station formerly maintained at Sonyea, Livingston County.

Drainage area.—74 square miles (measured on topographic maps).

Records available.—August 29, 1915, to October 31, 1917, when station was discontinued. July 22, 1910, to December 31, 1912, at former station at Sonyea.

Gage.—Staff, in two sections; inclined section graduated from 3.0 to 6.0 feet; vertical section graduated from 6.0 to 17.0 feet; read by Fred Mott and Mrs. Rose Feathers.

Discharge measurements.—Made from footbridge at gage or by wading.

Channel and control.—Gravel, probably fairly permanent.

Extremes of discharge.—1915–1917: Maximum stage recorded, 13.15 feet at 7 a. m. March 28, 1916 (discharge not determined); minimum stage recorded, 3.8 feet several times during October, 1916 (discharge practically zero).

Ice.—Stage-discharge relation affected by ice. Observations of stage suspended during winter.

Accuracy.—Stage-discharge relation probably permanent; affected by ice during large part of the period December to March. Rating curve well defined between 1 and 350 second-feet and fairly well defined between 350 and 1,300 second-feet. Gage read to half-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records fair.

Discharge measurements of Keshequa Creek near Sonyea, N. Y., during the year ending Sept. 30, 1917.

CANADICE LAKE OUTLET NEAR HEMLOCK, N. Y.

Location.—At foot of Canadice Lake, Livingston County. Outlet flows into Genesee River through Canadice Lake Outlet and Honeoye Creek.

Drainage area.—12.6 square miles, of which 1.0 square mile is lake surface.

Records available.—April, 1903, to September 30, 1917.

Gage.—Hook, in channel above weir.

Channel and control.—Outflow is measured over a standard thin-edged weir witn a 5-foot crest and two end contractions so arranged with needle timbers at the ends that the length may be increased to 14.96 feet. No end contractions during high water. The weir crest stands 3.14 feet above the stream channel, which is artificial with a plank bottom and vertical sides, and the crest is never submerged by back-water. Two additional rectangular gates, each one foot square with three complete contractions and a fourth incomplete contraction at the bottom.

Ice.—Stage-discharge relation not affected by ice as the pool above the weir is free from ice throughout the winter.

Diversions.—No water is diverted from Canadice Lake above the station.

Regulation.—Outflow of lake is regulated by bulkhead and gates at dam above weir.

Accuracy.—Stage-discharge relation permanent. Rating curve used is expressed by Francis formula. Corrections are made for velocity of approach for high stages. Gage read to hundredths once daily. Records good.

Cooperation.—Data collected, computed, and furnished for publication by the city engineer of Rochester.

Monthly discharge of Canadice Lake Outlet near Hemlock, N. Y., for the year ending Sept. 30, 1917.

Month.	Mean discharge.	Mean elevation of lake above low water mark.	Month.	Mean discharge.	Mean elevation of lake above low-water mark.
	Sec.-feet.	*Feet.*		*Sec.-feet.*	*Feet.*
October	0.096	1.328	May	13.170	2.211
November	2.085	1.269	June	20.156	2.287
December	3.634	.946	July	22.756	2.608
January	3.684	.965	August	4.197	2.135
February	3.934	1.032	September	3.320	1.788
March	16.289	2.144			
April	25.572	2.028	The year	9.908	1.728

Note.—Terminal water surface for year was 0.25 foot higher than that for the previous year, corresponding to a gain in storage of 7,508,350 cubic feet, or a discharge of 0.238 second-feet for the year. This correction applied to the above mean for the year gives 10.146 second-feet.

OWASCO LAKE OUTLET NEAR AUBURN, N. Y.

Location.—On the farm of Charles H. Pearce, 2 miles below center of Auburn, Cayuga County, and 3¾ miles below State dam at outlet of Owasco Lake.

Drainage area.—206 square miles (measured on topographic maps).

Records available.—November 17, 1912, to September 30, 1917.

Gage.—Gurley water-stage recorder in a concrete shelter on left bank, on the farm of Charles H. Pearce. Recorder inspected by Charles H. Pearce.

Discharge measurements.—Made by wading directly opposite the gage, or from a cable at same section.

Channel and control.—A low concrete control has been constructed about 15 feet below the gage. Crest of control is 1 foot wide and the slopes of both upstream and downstream faces are ½: 1. A small horizontal apron built on a level with the bed of the stream extends down stream 2½ feet from toe of dam. Mean elevation of the left end of the dam for a distance of 50 feet is gage height 1.28 feet; the remaining 50 feet of the crest of the dam is at a gage height 2.13 feet.

Extremes of discharge.—Maximum stage during year, from water-stage recorder, 3.47 feet from 8.15 to 8.30 a. m. June 30 (discharge, 1,070 second-feet); minimum stage not recorded.

1912-1917: Maximum stage, 6.4 feet during period March 25-30, 1913, determined by leveling from flood marks (discharge, 2,750 second-feet); minimum stage, from water-stage recorder, 1.41 feet at 1 a. m. October 15, 1915 (discharge, 5.6 second-feet).

Ice.—Stage-discharge relation seldom affected by ice.

Diversions.—An average flow of about 10 second-feet is pumped from Owasco Lake for the municipal water supply of the city of Auburn. Proportion returning to stream above the gaging station is not known.

Regulation.—Large diurnal fluctuation in flow during low-water periods due to operation of mills in the city of Auburn; seasonal flow regulated at the State dam.

Accuracy.—Stage-discharge relation permanent; not affected by ice during year. Rating curve well defined between 1 and 1,700 second-feet. Operation of the water-stage recorder satisfactory throughout year, except during periods indicated in footnote to daily-discharge table. Daily discharge ascertained by averaging the hourly discharge. Records excellent except for periods of no gage-height records and when there was leakage under control. See footnote to daily-discharge table.

Discharge measurements of Owasco Lake outlet near Auburn, N. Y., during the year ending Sept. 30, 1917.

NOTE.—During November a leak was discovered under the control, discharging between 20 and 25 second-feet. This was assumed to have started October 12. The leak was repaired November 5. Daily discharge Oct. 31 to Nov. 4 includes this leakage. Mean discharge estimated for following periods because recorder was not in operation: Oct. 13-30, 82.0 second-feet; Jan. 16-31, 135 second feet; Feb. 1-5, 155 second-feet; Feb. 11-19, 160 second-feet; March 9-16, 220 second-feet; May 17-25, 340 second-feet; June 15-22, 740 second-feet; Aug. 1-13, 230 second-feet. Discharge, July 31 and Aug. 31, estimated.

Monthly discharge of Owasco Lake outlet near Auburn, N. Y., for the year ending Sept. 30, 1917.

WEST BRANCH OF ONONDAGA CREEK AT SOUTH ONONDAGA, N. Y.

Location.—At highway bridge in South Onondaga, Onondaga County, about 1½ miles above mouth of creek and about 10 miles above Syracuse.

Drainage area.—20.8 square miles (measured on topographic maps).

Records available.—August 22, 1916, to September 30, 1917.

Gage.—Staff on downstream side of right abutment of bridge.

Discharge measurements.—Made from bridge or by wading.

Channel and control.—Fine and coarse gravel; probably shifting.

Extremes of stage.—Maximum stage recorded, 2.86 feet at 7.05 a. m. March 12; minimum stage recorded, 0.90 foot at 6.45 p. m. September 24 and 6.35 a. m. September 25.

Ice.—Stage-discharge relation probably affected by ice.

Data inadequate for determination of discharge.

Discharge measurements of West Branch of Onondaga Creek at South Onondaga, N. Y., during the year ending Sept. 30, 1917.

Note.—Observations suspended because of ice, Jan. 1 to Mar. 6.

BLACK RIVER NEAR BOONVILLE, N. Y.

Location.—At highway bridge about 1 mile above mouth of Sugar River, 2 miles northeast of Boonville, Oneida County, and 2 miles, by river, downstream from Hawkinsville.

Drainage area.—303 square miles (measured on topographic maps).

Records available.—February 16, 1911, to September 30, 1917.

Gage.—Chain near center of left span, downstream side of bridge; staff gage on right abutment used for high-water readings; read by W. D. Charbonneau.

Discharge measurements.—Made from a cable about half a mile above gage or by wading near the cable.

Channel and control.—Rough and full of boulders; permanent.

Extremes of discharge.—Maximum stage recorded during year, 9.8 feet at 4 p. m. June 12 (discharge, 5,240 second-feet); minimum stage recorded 3.02 feet at 4 p. m. August 5 (discharge 28 second-feet).

1911–1917: Maximum stage (determined by leveling from flood mark) about 12.5 feet during night of March 28, 1913 (discharge, about 10,000 second-feet); minimum stage recorded, 3 feet at 8 a. m. September 29 and November 8, 1913, and October 8, 1914 (discharge, 27 second-feet).

Ice.—Stage-discharge relation affected by ice.

Regulation and diversion.—The State dam at Forestport, about 8 miles upstream, provides a reservoir with a capacity of about 2,000,000,000 cubic feet. Water is diverted from this reservoir during the navigation season through the Forestport Feeder, flowing west to a basin in Boonville. The Black River canal flows north from this basin entering Black River at the foot of Lyons Falls. A spillway from the basin overflows into Mill Creek, a tributary of Black River. Water flowing through these two channels returns to the river below the gaging station, thus passing around it. The Black River canal also flows south from Boonville, passing out of the Black River drainage and entering the summit level of the Erie canal (or Barge canal) at Rome.

Occasional discharge measurements have been made at three points to indicate the distribution of the diverted water. The water entering Boonville through the Forestport Feeder has been measured at the highway bridge about 1 mile northeast of Boonville. During October, 1915, two water-stage recorders were installed on this canal to obtain a continuous record of flow, which is published as a separate station "Forestport Feeder near Boonville, N. Y." The water flowing north from the basin through the Black River canal has been measured at the highway bridge just below the lock into this canal near the railroad station. The water flowing south from the basin has been measured at a private farm bridge about 1 mile southeast of Boonville. During September, 1915, two water-stage recorders were installed on this canal to obtain a continuous record of the flow, which is published as a separate station, "Black River canal (flowing south) near Boonville, N. Y."

Accuracy.—Stage-discharge relation practically permanent; affected by ice during a large part of the period December to March, inclusive. Rating curve well defined between 35 and 2,800 second-feet and fairly well defined between 2,800 and 4,500 second-feet. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records good, except for periods when the stage-discharge relation was affected by ice, for which they are fair.

Discharge measurements of Black River near Boonville, N. Y., during the year ending Sept. 30, 1917.

The year	5,100	31	793	2.62	35.52

NOTE.—Water diverted past this station by the Forestport feeder is not included in the above table.

BLACK RIVER AT BLACK RIVER, N. Y.

LOCATION.—About one-fourth mile below concrete-arch highway bridge and power plant of Northern New York Utilities Co. and three-fourths mile below village of Black River, Jefferson County.

DRAINAGE AREA.—1,870 square miles (measured on topographic maps).

RECORDS AVAILABLE.—March 24 to September 30, 1917.

GAGE.—Vertical staff, in two sections, spiked to large cedar tree on left bank about one-fourth mile below highway bridge; read by Erwin W. Hart.

DISCHARGE MEASUREMENTS.—Made from cable about 100 yards above gage.

CHANNEL AND CONTROL.—Solid rock.

EXTREMES OF DISCHARGE.—Maximum stage recorded during period of record, 13.4 feet from 6 p. m. April 4 to 7 a. m. April 5 (discharge, 19,300 second-feet); minimum stage recorded, 1.05 feet at 2.45 p. m. July 29, when a current-meter measurement was made (discharge, about 16 second-feet).

ICE.—Stage-discharge relation probably not affected by ice.

REGULATION.—Seasonal distribution of flow is regulated by Beaver River flow, Fulton Chain lakes, Forestport reservoir and other storage reservoirs in the upper portion of the drainage basin. Some diurnal fluctuation at low stages due to mills and power plants above station.

DIVERSIONS.—Water is diverted from Black River into Forestport Feeder at Forestport. A portion of this water returns to river through various spillways and through Black River canal (flowing north). The remainder passes out of the drainage basin through Black River canal (flowing south); the record at the station on Black River canal (flowing south) at Boonville indicates the amount of this diversion. See also "Regulation and Diversion" in description of station on Black River near Boonville.

ACCURACY.—Stage-discharge relation permanent. Rating curve well defined between 500 and 18,000 second-feet. Gage read to tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records good except for days of low discharge, for which they may be poor.

Discharge measurements of Black River at Black River, N. Y., during the year ending Sept. 30, 1917.

NOTE.—See "Regulation" and "Diversion" in station description.

FORESTPORT FEEDER NEAR BOONVILLE, N. Y.

Location.—Slope station at lower end of feeder, above point where it enters the basin at Boonville, Oneida County.

Records available.—Occasional discharge measurements 1900 and 1905–1915; continuous record October 30, 1915, to September 30, 1917. Data published also in annual reports of New York State engineer and surveyor and State of New York Conservation Commission.

Gages.—Two Gurley seven-day water-stage recorders, with natural scale for gage heights. Gage No. 1 is at downstream end of left abutment of steel highway bridge in village of Hawkinsville; gage No. 2 is on left bank, just below a farm bridge about a mile above the basin at Boonville; they are 2.53 miles apart. The float wells are 1½ by 2 feet, inside dimensions, and the bottoms are about 1½ feet below normal elevation of water surface in canal. These gages and the two in the Black River canal (flowing south) near Boonville are all set at the same datum; recorder at gage No. 1 inspected by Mrs. Anna Zwahlen; that at gage No. 2 inspected by Charles Nugent.

Discharge measurements.—Made from the steel highway bridge at gage No. 1 in Hawkinsville.

Determination of discharge.—Daily discharge determined by use of Chezy formula. The coefficient, "C," is computed from each current-meter measurement and is plotted on a curve showing the variation of "C" through the season. A smooth curve drawn through the plotted points shows the coefficients for intervening days. The other factors in the Chezy formula are obtained from gage-height records and cross-section of the canal.

Diversions.—One spillway takes water from the Forestport feeder just below gage No. 2 and a second spillway takes water from the basin in Boonville. Both discharge into Mill Creek, which enters Black River below the Boonville gaging station. No spillway between gage No. 1 and gage No. 2. Other spillways in the feeder above gage No. 1 discharge into Black River above the gaging station. Therefore, this station indicates the total amount of water diverted past the gaging station on Black River near Boonville, and the sum of this record and the record for the Black River near Boonville indicates the total run-off of the Black River basin above these gaging stations.

Regulation.—Flow in the feeder is regulated at the outlet of Forestport reservoir.

Ice.—No flow in the canal during the winter season.

Accuracy.—Records good except for days on which discharge varies widely from the mean, for which they are fair.

Discharge measurements of Forestport feeder near Boonville, N. Y., during the year ending Sept. 30, 1917.

[a] Estimated.

BLACK RIVER CANAL (FLOWING SOUTH) NEAR BOONVILLE, N. Y.

LOCATION.—Slope station in summit level of Black River canal, near Boonville, Oneida County.

RECORDS AVAILABLE.—Occasional discharge measurements 1900 and 1905–1915; continuous record September 16, 1915, to September 30, 1917.

GAGES.—Two Gurley seven-day water-stage recorders with natural scale for gage heights; they are 1.81 miles apart. Gage No. 1 is on right bank (opposite towpath) about 50 feet downstream from collector's office in Boonville; gage No. 2 is on right bank (opposite towpath) about 300 yards above Lock 70 and 50 yards above spillway from the canal into Lansing Kill. These gages and the two gages in the Forestport feeder near Boonville are set to the same datum. Recorders inspected by Philip Joynt.

DISCHARGE MEASUREMENTS.—Made from the steel and concrete highway bridge in the village of Boonville, a short distance below gage No. 1.

Determination of discharge.—Daily discharge determined by use of Chezy formula. The coefficient "C" is computed from each current-meter measurement and plotted on a curve showing the variation of "C" through the season. A smooth curve drawn through the plotted points shows the coefficient for intervening days. The other factors in the Chezy formula are obtained from gage-height records and cross-section of canal.

Diversions.—No diversions between gage No. 1 and gage No. 2. Records obtained at this station indicate the quantity of water diverted for the canal from the Black River basin into the Mohawk River basin.

Regulation.—Flow in canal is regulated by operation of spillway and sluice gates at Lock 70 and also by discharge of Forestport feeder into the basin at Boonville.

Ice.—No flow in canal during winter season.

Accuracy.—Records good.

Discharge measurements of Black River canal (flowing south) near Boonville, N. Y., during the year ending Sept. 30, 1917.

MOOSE RIVER AT MOOSE RIVER, N. Y.

Location.—In the village of Moose River, Lewis County, about 3 miles downstream from McKeever, 5 miles below mouth of South Branch of Moose River, and nearly 20 miles above junction of Black and Moose rivers at Lyons Falls.

Drainage area.—370 square miles (measured on topographic maps).

Records available.—June 5, 1900, to September 30, 1917.

Gage.—Staff in two sections on left bank a short distance above the cable; read by Mrs. Martha Hannan and H. W. Hoch. Gage datum was lowered 0.17 foot February 28, 1903, and again 5.00 feet on January 1, 1913.

Discharge measurements.—Made from a cable a short distance below gage.

Channel and control.—Cobblestones and boulders; fairly permanent. Current smooth; depth comparatively uniform. Ice and logs occasionally jam above the station on a small island.

Extremes of discharge.—Maximum stage recorded during year, 13.2 feet at 8 a. m. June 12 (discharge, about 7,460 second-feet); minimum stage recorded 5.05 feet at 8 a. m. August 5 and 6 (discharge, 58 second-feet).

1900–1917: Maximum stage recorded, 16.3 feet during the afternoon of March 27, 1913, determined by leveling from flood marks (discharge, about 16,500 second-feet); minimum stage recorded, 4.94 feet July 21, 23, 25, 26, and 27, 1913 (discharge, about 42 second-feet).

Ice.—Stage-discharge relation affected by ice.

Regulation.—A timber dam at McKeever, 3 miles upstream, is used for power and for the regulation of flow during log driving. Seasonal distribution of flow affected by operation of the State dam at Old Forge. This regulation is indicated by a record from station "Middle Branch of Moose River at Old Forge."

Accuracy.—Stage-discharge relation practically permanent; affected by ice for a large part of the period from December to March. Rating curve fairly well defined between 100 and 5,500 second-feet. Gage read to half-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records fairly good except for periods when the discharge is low or the stage-discharge relation is affected by ice for which they are fair.

Discharge measurements of Moose River at Moose River, N. Y., during the year ending Sept. 30, 1917.

MIDDLE BRANCH OF MOOSE RIVER AT OLD FORGE, N. Y.

Location.—About 300 feet below highway bridge and 400 feet below State dam at Old Forge, Herkimer County.

Drainage area.—51.5 square miles (measured on topographic maps).

Records available.—November 9, 1911, to September 30, 1917.

Gage.—Vertical staff on left bank 300 feet below highway bridge; read by Jacob Edick.

Discharge measurements.—Made from highway bridge or by wading near gage.

Channel and control.—Bed near gage composed of stone and gravel. Control is rock ledge about 200 feet below gage; practically permanent.

Extremes of discharge.—Maximum stage recorded during year, 3.9 feet at 8 a. m. and 5 p. m. June 16 (stage-discharge relation affected by backwater from Moose River). Maximum discharge, 405 second-feet, computed from records at Old Forge dam. Minimum stage occurs when the gates of the dam are closed, discharge being due to leakage and discharge through the fish hatchery.

1911–1917: Maximum stage recorded, 6.3 feet March 28, 1913; stage-discharge relation affected by backwater from Moose River; discharge computed from records at dam, 760 second-feet.

Ice.—Stage-discharge relation not affected by ice.

Regulation.—Flow controlled by dam.

Accuracy.—Stage-discharge relation practically permanent between dates of shift; not affected by ice. Rating curve well defined from 20 to 400 second-feet. Gage read to hundredths twice daily. Daily discharge ascertained by applying to rating table mean daily gage height weighted on days of changing gates from records of gate opening at dam. Records good except those computed from gate openings at the dam, which are fair.

Discharge measurements of Middle Branch of Moose River at Old Forge, N. Y., during the year ending Sept. 30, 1917.

BEAVER RIVER AT STATE DAM NEAR BEAVER RIVER, N. Y.

LOCATION.—At concrete storage dam at outlet of Beaver River flow, about 7½ miles west of Beaver River postoffice, Herkimer County, and 7 miles above Beaver Lake at Number Four.

DRAINAGE AREA.—176 square miles (measured on topographic maps).

RECORDS AVAILABLE.—May 11, 1908, to September 30, 1917.

GAGES.—Elevation of water surface in the reservoir is determined by a staff gage in two sections, on the west corner of the gage house; read by James Dunbar, gate tender. The mean elevation of the crest of the spillway is at gage height 16.96 feet. Prior to September 28, 1913, elevation of water surface was determined by measuring the distance from the water surface to a reference point set at the elevation of the crest of the spillway. Widths of sluice gate openings determined by measuring on the gate stems the distance they have been raised.

DISCHARGE MEASUREMENTS.—Current-meter measurements made from a temporary foot bridge at the mouth of the outlet tunnel, below the gates. Discharge over the spillway has not been measured.

DETERMINATION OF DISCHARGE.—Records include the discharge through one or more of four 4-foot circular sluice gates, when opened, the discharge over the spillway, and the discharge through the logway at the west end of the spillway. The sluice gates have been rated by current-meter measurements made at different lake elevations but no measurements have been made of the discharge over the spillway or through the logway. Theoretic coefficients based on the Cornell experiments [1] have been used to compute ratings for the spillway and logway.

REGULATION.—At ordinary stages the discharge of Beaver River is completely regulated by the operation of the sluice gates.

EXTREMES OF STAGE.—Maximum elevation of water surface in reservoir recorded during year, 18.8 feet on April 22; minimum stage recorded 4.5 feet on October 19.

1908–1917: Maximum elevation of water surface in reservoir, 19.46 feet March 29, 1913; minimum stage, 2.9 feet September 29 and October 1, 1913.

EXTREMES OF DISCHARGE.—Maximum daily discharge during year, 1,960 second-feet April 23; minimum discharge, zero, during periods when gates were closed and there was no flow over spillway.

1908–1917: Maximum discharge, 3,300 second-feet on May 2, 1911.

ACCURACY.—Stage-discharge relation permanent; probably not affected by ice. Rating curves for sluice gates well defined. Lake gage read to half tenths once daily. The accuracy of computations depends to a large extent on the care with which the gates were set to the recorded openings. Records fair.

Discharge measurements of Beaver River at State dam near Beaver River, N. Y., during the year ending Sept. 30, 1917.

STREAMS TRIBUTARY TO ST. LAWRENCE RIVER.

EAST BRANCH OF OSWEGATCHIE RIVER AT NEWTON FALLS, N. Y.

LOCATION.—600 feet below lower dam of Newton Falls Paper Co., in Newton Falls, St. Lawrence County, 4 miles above mouth of Little River and 10 miles below outlet of Cranberry Lake.

DRAINAGE AREA.—166 square miles (measured by engineers of New York Conservation Commission).

RECORDS AVAILABLE.—October 6, 1912, to September 30, 1917.

GAGE.—Vertical staff on left bank 600 feet above lower dam; read by Alfred Renaud and Henay Van Waldick.

DISCHARGE MEASUREMENTS.—Made by wading, or from cable 30 feet upstream from gage.

CHANNEL AND CONTROL.—Small boulders and rock covered with waste from pulp mill; practically permanent.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 3.8 feet at 6.30 p. m. June 12 and 14 (discharge, 894 second-feet); minimum stage is reached nearly every Sunday during low-water period when paper mills shut down.

1912–1917; maximum stage recorded, 6.1 feet at 5.15 p. m. March 28, 1913 (discharge, 2,200 second-feet).

ICE.—Stage-discharge relation affected by ice only for a short time during extremely cold weather.

REGULATION.—Some diurnal fluctuation in flow caused by operation of paper mills. Seasonal flow largely controlled by storage at Cranberry Lake.

ACCURACY.—Stage-discharge relation practically permanent; not affected by ice during year. Rating curve well defined between 20 and 1,200 second-feet. Gage read to hundredths twice daily. Daily discharge ascertained by applying to the rating table weighted mean gage height based on observer's notes concerning operation of paper mills. Records good.

The following discharge measurement was made through incomplete ice cover by A. H. Davison:

January 18, 1918: Gage height, 1.83 feet; discharge, 282 second-feet.

Daily discharge, in second-feet, of East Branch of Oswegatchie River at Newton Falls, N. Y., for the year ending Sept. 30, 1917.

NOTE.—Table shows run-off as regulated at Cranberry Lake and by paper mills at Newton Falls.

OSWEGATCHIE RIVER NEAR HEUVELTON, N. Y.

LOCATION.—2½ miles above Heuvelton, St. Lawrence County, 3 miles below Rensselaer Falls, and 7 miles above mouth of Indian River (outlet to Black Lake).

DRAINAGE AREA.—961 square miles (measured on topographic maps).

RECORDS AVAILABLE.—June 23, 1916, to September 30, 1917.

GAGE.—Gurley seven-day water-stage recorder on the right bank, about 2½ miles above Heuvelton, installed September 16, 1916. Prior to this date gage height was determined by measuring the distance from a reference point to the water surface. Recorder inspected by George Todd.

CHANNEL AND CONTROL.—Solid rock.

EXTREMES OF DISCHARGE.—Maximum stage, from water-stage recorder, 7.6 feet from 9 to 12 a. m. March 30 (discharge, 11,700 second-feet); minimum stage from water-stage recorder, 0.91 foot at 11 p. m. October 16 (discharge 320 second-feet).

ICE.—Stage-discharge relation slightly affected by ice.

REGULATION.—Some diurnal fluctuation due to operation of mills at Rensselaer Falls and above. Seasonal flow regulated by storage in Cranberry Lake.

ACCURACY.—Stage-discharge relation permanent except as affected by ice January 11 to March 22. Rating curve well defined between 400 and 15,000 second-feet. Operation of water-stage recorder satisfactory throughout the year. Daily discharge June 23 to September 15, 1916, ascertained by applying to rating table daily gage height obtained from two observations of stage per day; discharge September 16, 1916, to September 30, 1917, except for period of ice effect, ascertained by applying to rating table mean daily gage height obtained from gage-height graph. Open-water records good; winter records fair.

Discharge measurements of Oswegatchie River near Heuvelton, N. Y., during the year ending Sept. 30, 1917.

NOTE.—Discharge, Sept. 22 and 23, 1916, estimated. Discharge, Jan. 11 to Mar. 24, estimated, because of ice, from discharge measurements, weather records, study of gage height graph, and comparison with open-water records for Harrisville. Discharge Sept. 23-27, 1917, estimated at 500 second-feet.

Monthly discharge of Oswegatchie River near Heuvelton, N. Y., for the period July 1, 1916, to Sept. 30, 1917.

[Drainage area, 961 square miles.]

WEST BRANCH OF OSWEGATCHIE RIVER NEAR HARRISVILLE, N. Y.

Location.—At highway bridge near Geers Corners, 2½ miles downstream from Harrisville, Lewis County.

Drainage area.—245 square miles (measured on topographic maps and map of New York, issued by U. S. Geol. Survey; scale, 1:500,000).

Records available.—July 1, 1916, to September 30, 1917.

Gage.—Vertical staff in three sections on the right bank; section graduated from 0.0 to 3.3 feet about 25 feet below bridge, and two sections graduated from 3.3 to 10.1 feet, on downstream side of bridge abutment. Gage read by Frank Osborne.

Discharge measurements.—Made from cable 200 feet upstream from bridge, or by wading.

Channel and control.—Rocky and rough; probably permanent.

Extremes of discharge.—Maximum stage recorded during year, 8.1 feet at 6.30 a. m. and 6 p. m. March 28 (discharge, 4,880 second-feet); minimum stage recorded, 1.10 feet at 6 p. m. August 11 (discharge, 42 second-feet).

Ice.—Stage-discharge relation probably not affected by ice.

Regulation.—Operation of pulp mill at Harrisville causes some diurnal fluctuation.

Accuracy.—Stage-discharge relation practically permanent; not affected by ice. Rating curve well defined between 50 and 4,000 second-feet. Gage read to half tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records good.

Discharge measurements of West Branch of Oswegatchie River near Harrisville, N. Y., during the year ending Sept. 30, 1917.

RAQUETTE RIVER AT PIERCEFIELD, N. Y.

LOCATION.—Half a mile below dam of International Paper Co. at Piercefield, St. Lawrence County, and about three-fourths mile above head of Black Rapids.

DRAINAGE AREA.—723 square miles (all but 16 square miles measured on topographic maps).

RECORDS AVAILABLE.—August 20, 1908, to September 30, 1917.

GAGE.—Stevens water-stage recorder installed October 22, 1912 in a galvanized sheet-iron house over a concrete well on right bank about one-half mile below dam. Prior to January 1, 1913, the following gages were used: August 20, 1908 to August 20, 1910, vertical staff fastened to an old pine stump; August 20, 1910, to December 31, 1912, chain fastened to same stump and having same datum until June 1, 1911, when datum of chain gage was lowered 2 feet. Water-stage recorder was set at this datum. Recorder inspected by M. O. Wood.

DISCHARGE MEASUREMENTS.—Made from a cable three-fourths mile below gage, just above Black Rapids.

CHANNEL AND CONTROL.—Channel opposite gage is a deep pond with no perceptible velocity. Control is at head of Black Rapids.

EXTREMES OF DISCHARGE.—Maximum stage during year, from water-stage recorder, 9.75 feet at 9 a. m. April 30 (discharge, 4,950 second-feet); minimum stage, from water stage recorder, 1.69 feet at 6 p. m. October 29 (discharge, 48 second-feet.)

1908–1917: Maximum stage, from water-stage recorder, 11.68 feet at 3 a. m. April 1, 1913 (discharge, 7,100 second-feet); minimum stage, from water-stage recorder, 0.85 foot at 11 a. m. September 2, 1913 (discharge, about 10 second-feet).

ICE.—Rapids that form control rarely freeze; measurements made when the pond was covered with ice indicate that the stage-discharge relation was not affected.

REGULATION.—Large diurnal fluctuation in flow caused by operation of dam during low and medium stages. Numerous lakes in upper part of drainage basin afford considerable storage, most of which is so controlled, that the effect on the seasonal distribution of flow is large.

ACCURACY.—Stage-discharge relation practically permanent; not affected by ice. Rating curve well defined between 50 and 7,000 second-feet. Operation of water-stage recorder satisfactory throughout the year. Daily discharge ascertained by use of discharge integrator. Records good.

COOPERATION.—Water-stage recorder inspected by an employee of the International Paper Co.

Discharge measurements of Raquette River at Piercefield, N. Y., during the year ending Sept. 30, 1917.

The year	4,900	62	1,320	1.83	24.78

NOTE.—Minimum discharge for each month occurred on Sunday.

ST. REGIS RIVER AT BRASHER CENTER, N. Y.

Location.—Near steel highway bridge in Brasher Center, St. Lawrence County, 5 miles downstream from Brasher Falls, 6½ miles below junction of East and West branches of St. Regis River and about 12 miles above mouth.

Drainage area.—621 square miles (measured on Post Route map).

Records available.—August 22, 1910, to September 30, 1917.

Gages.—Staff, with inclined and vertical sections, on right bank about 600 feet above bridge; installed June 24, 1916. Prior to this date, chain on right-hand downstream side of bridge. Gages not at same datum; subject to different controls. Gage read by George Myers.

Discharge measurements.—Made from a cable at the staff gage, installed in June 1916. Previously made from the highway bridge, or by wading.

Channel and control.—Bed at cable composed of small boulders and coarse gravel; large boulders and gravel, and very rough at bridge; fairly permanent.

Extremes of discharge.—Maximum stage recorded during year, 9.58 feet at 5 p. m. April 3 (discharge, 6,030 second-feet); minimum stage recorded 5.25 feet at 5 p. m. August 8 (discharge about 34 second-feet).

1910–1917: Maximum stage recorded, 9.1 feet at 7 a. m. March 27, 1914 (discharge, 16,200 second-feet); minimum stage recorded, August 8, 1917.

Ice.—Stage-discharge relation seriously affected by ice.

Accuracy.—Stage-discharge relation practically permanent, except as affected by ice December 12 to March 25. Rating curves well defined between 200 and 6,000 second-feet. Gage read to quarter-tenths twice daily. Daily discharge, except for period of ice effect, ascertained by applying mean daily gage height to rating table. Open-water records good; winter records fair.

Discharge measurements of St. Regis River at Brasher Center, N. Y., during the year ending Sept. 30, 1917.

RICHELIEU RIVER AT FORT MONTGOMERY, ROUSES POINT, N. Y.

LOCATION.—Inside the fort, three-eighths mile south of international boundary, about half a mile below outlet of Lake Champlain, and 1 mile northeast of Rouses Point, Clinton County.

DRAINAGE AREA.—7,870 square miles, including 436 square miles of water surface (from annual report of New York State Engineer and Surveyor).

RECORDS AVAILABLE.—1875 to 1917.

GAGE.—Staff, inside of fort; read by Thomas Bourke. Elevation of gage zero, 92.50 feet above mean sea level.

EXTREMES OF STAGE.—Maximum elevation recorded during year, 98.25 feet at 10 a. m. April 8 and 9; minimum elevation recorded, 93.3 feet at 10 a. m. November 20 and 21.

1869–1917: Maximum elevation recorded, 103.28 feet April, 1869;[1] minimum elevation recorded, 91.9 feet November 13, 1908.

COOPERATION.—Gage heights observed under direction of the Corps of Engineers of the United States Army and reported weekly to the United States Geological Survey.

Daily gage height, in feet, of Richelieu River at Fort Montgomery, Rouses Point, N. Y., for the year ending Sept. 30, 1917.

SARANAC RIVER NEAR PLATTSBURG, N. Y.

LOCATION.—At Indian Rapids power plant (formerly known as Lozier dam) of Plattsburg Gas & Electric Co., about 6 miles above mouth of river at Plattsburg, Clinton County.

DRAINAGE AREA.—607 square miles (measured on topographic maps).

RECORDS AVAILABLE.—March 27, 1903, to September 30, 1917.

[1] Hoyt, J. C., Stream measurements, 1903, North Atlantic, St. Lawrence River and Great Lakes drainage: U. S. Geol. Survey Water-Supply Paper 97, p. 340, 1904.

GAGES.—Crest gage a vertical staff on the angle of the wing wall at the end of the racks. Datum raised 0.76 foot August 20, 1906. Tailrace gage a vertical staff spiked to timber work dike between tailrace and river and about 50 feet below power house. Records of kilowatt output are obtained by watt meter on switchboard at half-hour intervals. Inclined staff gage at cable station, a quarter of a mile below dam. Gages and watt meters read by power-house operators.

DISCHARGE MEASUREMENTS.—Made from a cable at head of Indian Rapids, one quarter mile below dam. Low-water measurements made by wading under cable or in tailrace.

DISCHARGE RATING.—Records include flow over concrete spillway 171.25 feet in crest length, a rating for which has been prepared for use of coefficients[a] derived from experiments made in the hydraulic laboratory of Cornell University on a model section of the dam; the discharge through two power units equipped with 300 kilowatt generators which have been rated by current meter measurements; and the discharge through two 5-foot waste gates when open. Occasional observations are made on the inclined staff gage at the cable as a check on the ratings of spillway and turbines.

EXTREMES OF DISCHARGE.—Maximum daily discharge during year, 5,400 second-feet April 3; minimum daily discharge 100 second-feet August 29.

1908–1917: Maximum daily discharge recorded, 6,410 second-feet, April 20, 1914; minimum daily discharge recorded, 90 second-feet, September 28, 1914.

SPECIAL STUDY.—A portable water-stage recorder was operated at the cable for a short period in July, 1914. Mean daily discharge computed from its record agreed very closely with mean daily discharge derived from power-plant ratings.

ICE.—The crest of the spillway is kept free from ice so that the stage-discharge relation is not affected.

REGULATION.—The lakes and ponds on the main stream and tributaries above the station comprise a water surface area of about 25.5 square miles. The actual storage afforded by these reservoirs has been largely increased by the State dam at Lower Saranac Lake, the operation of which affects the distribution of flow throughout the year.

ACCURACY.—Discharge measurements made during the year indicate that the ratings of spillway and turbines have not changed. Discharge over the spillway ascertained by applying to rating table mean gage heights for 6-hour periods. Discharge through the turbines ascertained by applying to their ratings, the mean kilowatt output and head for 12-hour periods. Records fair.

COOPERATION.—Gage-height records and watt meter readings furnished by Plattsburg Gas & Electric Co., Herbert A. Stutchbury, superintendent.

Discharge measurements of Saranac River near Plattsburg, N. Y., during the year ending Sept. 30. 1917.

[a] Sunday.

AUSABLE RIVER AT AUSABLE FORKS, N. Y.

Location.—In village of Ausable Forks, Clinton County, immediately below junction of East and West branches and about 15 miles above mouth of river.

Drainage area.—444 square miles (measured on topographic maps).

Records available.—August 17, 1910, to September 30, 1917.

Gage.—Chain on left bank 1,000 feet below junction of East and West branches; read by A. S. Baker.

Discharge measurements.—Made from a cable 1½ miles below gage, or by wading either near the cable or a short distance above the gage.

Channel and control.—Stone and gravel; occasionally shifting. Channel divided by an island opposite the gage.

Extremes of discharge.—Maximum stage recorded during year, 6.95 feet at 6 p. m., April 2 (discharge, 7,580 second-feet); minimum discharge, 110 second-feet, February 18.

1910–1917: Maximum stage recorded, 10.2 feet in the evening of March 27, 1913 (discharge, roughly 25,000 second-feet); minimum stage recorded, 3.0 feet at 7 a. m. July 21, 1912 (discharge, practically zero).

Special study.—A portable water-stage recorder was installed at this station and a continuous gage-height record obtained July 11 to September 30, 1914, which showed a continual small fluctuation in stage, It was shown that monthly mean discharge based on a semidaily gage heights is in error as follows: July 11–31, 3.5 per cent; August, 4.1 per cent; September, 1914, 0.5 per cent. Some of the determinations of daily discharge showed greater errors, but these were largely compensating.

Ice.—Stage-discharge relation slightly affected by ice.

Accuracy.—Stage-discharge relation probably permanent between dates of shifting; affected by ice for short periods from December to March. Rating curve fairly well defined between 175 and 3,000 second-feet. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records good.

Discharge measurements of Ausable River at Ausable Forks, N. Y., during the year ending Sept. 30, 1917.

WEST BRANCH OF AUSABLE RIVER NEAR NEWMAN, N. Y.

Location.—On farm of James Dudley, about 4 miles northeast of Newman, Essex County, and 4 miles below confluence at Lake Placid.

Drainage area.—116 square miles (measured on topographic maps).

Records available.—June 7, 1916, to September 30, 1917.

Gage.—Staff, in two sections, on the right bank near the residence of Mr. Dudley. Lower section is inclined, graduated from 1.0 to 6.5 feet; the upper section is vertical graduated from 6.55 to 10.1 feet; read by James Dudley.

Discharge measurements.—Made by wading or from cable 300 feet above gage.

Channel and control.—Solid rock.

Extremes of stage.—Maximum stage recorded, 6.2 eet at 6 p. m. June 22; minimum stage recorded, 1.7 feet at 7 p. m. June 28.

Data inadequate for determination of discharge.

Discharge measurements of West Branch of Ausable River near Newman, N. Y., during the year ending Sept. 30, 1917.

Note.—Gage-height observations suspended because of ice, Jan. 1 to Apr. 30.

LAKE GEORGE AT ROGERS ROCK, N. Y.

Location.—At boathouse in a small bay on north side of steamboat landing at Rogers Rock, Essex County.

Drainage area.—Not measured.

Records available.—July 10, 1913, to September 30, 1917.

Gage.—Vertical staff fastened to a pile in the back end of the boathouse. Datum 3.15 feet[1] below crest of dam at outlet of lake; read once daily by George O. Cook.

Extremes of stage.—Maximum stage recorded during year, 4.05 feet June 14, 15, 16, and 21; minimum stage recorded, 1.2 feet on November 21 and December 22.

1913–1917 maximum stage recorded, 4.98 feet on May 2, 1914; minimum stage recorded 1.2 feet on November 21 and December 22, 1916.

Regulation.—The elevation of lake surface is regulated by the operation of gates and wheels at the dam at the outlet of the lake at Ticonderoga.

Cooperation.—Gage-height record for current year furnished by International Paper Co.

Daily gage height, in feet, of Lake George at Rogers Rock, N. Y., for the year ending Sept. 30, 1917.

LAKE CHAMPLAIN AT BURLINGTON, VT.

Location.—On south side of roadway leading to dock of Champlain Transportation Co., at foot of King street, Burlington.

Records available.—May 1, 1907, to September 30, 1917.

Gage.—Staff. Comparisons of gage readings indicate that zero of gage at Burlington is at practically the same elevation as that of gage at Fort Montgomery—92.5 feet above mean sea level. Gage read by employee of the Champlain Transportation Co.

[1] Determined by levels; supersedes the estimated datum previously published.

EXTREMES OF STAGE.—Maximum stage recorded during year, 6.20 feet April 10–11; minimum stage recorded, 0.95 foot November 24–25.

1907–1917: Maximum stage recorded, 8.20 feet on April 7, 1913; minimum stage recorded, −0.25 foot on December 4, 1908.

ICE.—Wider portions of lake not usually frozen over until the last part of January. Occasionally closure does not occur until February and in some years it lasts only for a few days. The northern end of the lake, above the outlet, is usually covered with ice from the middle of December to the middle of April.

ACCURACY.—Gage read to hundredths once a day except on Sundays; readings during winter at irregular intervals. Gage readings made when the lake is rough subject to inaccuracies due to wave action.

COOPERATION.—Gage-height record furnished through the courtesy of Mr. D. A. Loomis, general manager of the Champlain Transportation Co.

Daily gage height, in feet, of Lake Champlain at Burlington, Vt., for the year ending Sept. 30, 1917.

NOTE.—Thickness of ice 100 feet from dock: Jan. 29, 5 inches; Feb. 5, 9 inches; Feb. 12, 12.5 inches; Feb. 19, 15.75 inches; Feb. 26, 17 inches; Mar. 6, 17.5 inches; Mar. 13, 17.75 inches; Mar. 20, 16.75 inches; Mar. 26, 13 inches.

OTTER CREEK AT MIDDLEBURY, VT.

LOCATION.—At railroad bridge half a mile south of railroad station at Middlebury, Addison County, 3½ miles below mouth of Middlebury River, and 3½ miles above mouth of New Haven River.

DRAINAGE AREA.—615 square miles.

RECORDS AVAILABLE.—April 1, 1903, to May 1, 1907; October 5, 1910, to September 30, 1917.

GAGE.—Chain; read by Alexander Hamilton.

DISCHARGE MEASUREMENTS.—Made from a boat just below railroad bridge, at the stone-arch highway bridge just above dam, or by wading.

CHANNEL AND CONTROL.—Channel deep; current sluggish for several miles above the station. Control for low stages is gravel and boulder rips about 800 feet below gage, probably somewhat shifting; control at high stages is near the dam 800 feet farther downstream.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 16.3 feet at 7.15 a. m. April 2 (discharge 3,680 second-feet); minimum stage recorded during year, 11.65 feet at 7.15 a. m. October 9 (discharge, 175 second-feet).

1903–1907 and 1910–1917: Maximum stage recorded, 21.07 feet March 30, 1913 (discharge, from extension of rating curve, about 8,000 second-feet); minimum open-water stage recorded, 11.45 feet September 15, 1913 (discharge, 138 second-feet). A somewhat lower discharge has probably occurred at various times when the stage-discharge relation has been affected by ice.

ICE.—Ice forms to a considerable thickness at the gage and occasionally at the control, affecting the stage-discharge relation.

REGULATION.—Probably little if any effect from power developments above the station. Considerable storage has been developed on tributaries near the headwaters.

ACCURACY.—Stage-discharge relation has changed somewhat in previous years, but apparently no change during 1916–17. Rating curve well defined between 200 and 4,000 second-feet. Gage read to quarter-tenths once daily. Daily discharge ascertained by applying daily gage height to rating table, with corrections for ice during winter as shown in foot note to daily discharge table. Records good.

Discharge measurements of Otter Creek at Middlebury, Vt., during the year ending Sept. 30, 1917.

WINOOSKI RIVER AT MONTPELIER, VT.

LOCATION.—One mile downstream from Central Vermont Railway station in Montpelier, Washington County, about three eighths of a mile above mouth of Dog River, and 1¼ miles below mouth of Worcester Branch.

DRAINAGE AREA.—420 square miles.

RECORDS AVAILABLE.—May 19, 1909, to September 30, 1917.

GAGE.—Gurley seven-day water-stage recorder installed July 4, 1914, on right bank; gage heights referred to datum by means of a hook gage inside the well; an outside staff gage is used for auxiliary readings; records June 16 to July 3, 1914, obtained from the staff gage. Chain gage at highway bridge just above the Central Vermont Railway station used from May 19, 1909, to June 30, 1914.

DISCHARGE MEASUREMENTS.—Made from a cable or by wading.

CHANNEL AND CONTROL.—Channel deep and fairly uniform in section at the gage, control is formed by sharply defined rock outcrop about 500 feet below gage.

EXTREMES OF DISCHARGE.—Maximum open-water stage during year, from water-stage recorder, 12.52 feet at 9 a. m. March 28 (discharge, from extension of rating curve, 10,600 second-feet); minimum stage from water-stage recorder, 2.96 feet at 6 a. m. October 18, and 7 a. m. November 1 (discharge 43 second-feet).

1909–1917: Maximum stage, determined by leveling from flood marks preserved on building near present gage, 17.31 feet, April 7, 1912 (discharge not determined); minimum stage from water-stage recorder, 1914-1917, 2.77 feet, August 13, 1914 and October 24, 1915 (discharge, 19 second-feet).

ICE.—Stage-discharge relation seriously affected by ice during the winter. Discharge ascertained by means of gage heights, current meter measurements, observer's notes, and weather records.

REGULATION.—Operation of power plants on main stream and tributaries above station cause large diurnal fluctuations in stage (see Water-Supply Paper 424, fig. 1, p. 41).

ACCURACY.—Stage-discharge relation practically permanent except when affected by ice. Rating curve well defined between 30 and 5,000 second-feet. Operation of water-stage recorder satisfactory during the year. Daily discharge determined by discharge integrator, except for high stages and during the period December to March, when mean daily gage heights were used. Open-water records good; winter records fair.

Discharge measurements of Winooski River at Montpelier, Vt., during the year ending Sept. 30, 1917.

DOG RIVER AT NORTHFIELD, VT.

Location.—At highway bridge near Norwich University campus in Northfield, Washington County. Union Brook joins Dog River a short distance below station.

Drainage area.—47 square miles (from surveys made by Norwich University students).

Records available.—May 14, 1909, to September 30, 1917. Records from May 14, 1909, to August 22, 1910, obtained at lower highway bridge; those from August 23, 1910, to date at present location.

Gages.—Gurley 7-day water-stage recorder; gage heights referred to gage datum by means of a hook gage inside the well; outside staff gage used for auxiliary readings.

Discharge measurements.—Made from highway bridge or by wading.

Channel and control.—Channel composed of gravel and alluvial deposits; subject to slight shifts.

Extremes of discharge.—Maximum stage during year, from water-stage recorder, 5.78 feet at 12.30 a. m. March 28 (discharge, 1,440 second-feet); minimum stage during year, from water-stage recorder, 0.92 foot several times in August and September (discharge, 7.8 second-feet).

1910–1917: Maximum stage recorded at present site, 8.5 feet March 25, 1913 (discharge, 3,400 second-feet); minimum stage recorded, 0.60 foot September 10 and 11, 1913 (discharge, 3.0 second-feet). At the lower gage, 1909–10 flow was practically zero at various times when water was held back by dam above gage.

Ice.—River frozen over during winter.

Accuracy.—Stage-discharge relation fairly permanent except when affected by ice. Rating curve well defined below 500 second-feet and poorly defined above. Operation of water-stage recorder satisfactory throughout year except for periods as shown in footnote to daily-discharge table. Daily discharge ascertained by applying to rating table mean daily gage height obtained by inspecting gage-height graph. Records good, except those from November to March, which are estimated as stated in footnote to monthly-discharge table.

Discharge measurements of Dog River at Northfield, Vt., during the year ending Sept. 30, 1917.

a Estimated.

NOTE.—Mean discharge, Nov. 15 to Mar. 11, estimated from a comparative study of two discharge measurements, and records of flow for White and Winooski rivers.

LAMOILLE RIVER AT CADYS FALLS, VT.

LOCATION.—About one-fourth mile below power house of Morrisville municipal electric plant, at what was formerly known as Cadys Falls, 2 miles downstream from Morrisville, Lamoille County.

DRAINAGE AREA.—280 square miles.

RECORDS AVAILABLE.—September 4, 1913 to September 30, 1917. A station was maintained at highway bridge near power plant at Cadys Falls from July 28, 1909, to July 13, 1910.

GAGES.—Barrett & Lawrence water-stage recorder in gage house on right bank, one-fourth mile below highway bridge at Cadys Falls, used to December 28, 1916; Friez water-stage recorder after December 29, 1916. Gage heights are referred to gage datum by means of a hook gage inside the well. An outside staff gage is used for auxiliary readings. From July 28, 1909, to July 13, 1910, chain gage on highway bridge was used.

DISCHARGE MEASUREMENTS.—Made from a cable or by wading.

CHANNEL AND CONTROL.—Bed smooth gravel. Well-defined gravel control 500 feet downstream from gage.

EXTREMES OF DISCHARGE.—Maximum stage during year from water-stage recorder, 8.36 feet at 9.30 a. m. June 12 (discharge, 4,520 second-feet); minimum stage during year, from water-stage recorder, 1.95 feet at 3 a. m. Sept. 18 (discharge, 74 second-feet).

1913–1917: Maximum stage recorded, 10.53 feet April 20, 1914, (discharge 7,250 second-feet); minimum stage recorded, 1.82 feet, August 17, 1914 (discharge, 50 second-feet).

ICE.—River freezes over for short periods during extremely cold weather; stage-discharge relation slightly affected by ice.

ACCURACY.—Stage-discharge relation practically permanent, except when affected by ice. Rating curve well defined. Operation of water-stage recorder satisfactory throughout year except for short periods as shown in footnote to daily-discharge table. Daily discharge ascertained by applying to rating table mean daily gage height obtained by inspecting gage-height graph, October 1 to April 30; by discharge integrator after May 1. Records good.

Discharge measurements of Lamoille River at Cadys Falls, Vt., during the year ending Sept. 30, 1917.

GREEN RIVER AT GARFIELD, VT.

LOCATION.—At site of old dam above highway bridge at Garfield village, town of Hyde Park, Lamoille County. Green River is tributary to Lamoille River about 4 miles east of Morrisville.

DRAINAGE AREA.—20 square miles (roughly approximate).

RECORDS AVAILABLE.—January 3, 1915, to September 30, 1917.

GAGE.—Inclined staff on left bank in pool back of weir; read by P. M. Trescott.

DISCHARGE MEASUREMENTS.—Standard sharp-crested weir of compound section length of crest at gage height 0.00 is 9.0 feet; at gage height 0.83 foot, length of crest is increased 11.17 feet. Current-meter measurements made at footbridge about one-half mile downstream from weir, and at highway bridge about one-half mile above weir.

CHANNEL AND CONTROL.—A pool of considerable size is formed in the old mill pond back of the weir; at ordinary stages the velocity of approach to the weir is very small. Some water leaks around the weir in the old tail-race on left bank.

EXTREMES OF DISCHARGE.—Maximum stage during year, 3.12 feet at 9 a. m. April 22 (discharge, from extension of rating curve about 325 second-feet); minimum stage during year, 0.45 foot several times in February (discharge, 9.3 second-feet).

1915–1917: Maximum stage recorded, 3.6 feet at 9 a. m. April 22, 1915 (discharge from extension of rating curve, about 435 second-feet); minimum stage recorded, 0.35 foot at 9 a. m. February 5, 1915 (discharge, 6.3 second-feet). Rating curve revised since publication of report for 1916.

ICE.—Weir and weir crest kept clear of ice by clear fall below; stage-discharge relation not affected by ice.

REGULATION.—An old timber dam about 2 miles upstream affects flow to some extent. The dam leaks by an amount somewhat greater than the low-water flow. During prolonged low stages the surface of water in pond (103 acres) falls below crest of dam; subsequent increased flow into pond is retained until water again flows over crest, when the increased flow is apparent at gaging station.

ACCURACY.—Stage-discharge relation practically permanent. Rating curve based on weir formula, $Q=3.33\ LH^{3/2}$, with corrections determined from current-meter measurements, and with logarithmic extension above gage height 1.90 feet. Gage read twice daily to hundredths. Daily discharge ascertained by applying mean daily gage height to rating table. Records good below 130 second-feet; at the higher stages the weir is flooded and records are somewhat uncertain.

COOPERATION.—Gage-height records furnished by C. T. Middlebrook, consulting engineer, Albany, N. Y.

Discharge measurements of Green River at Garfield, Vt., during the year ending Sept. 30, 1917.

MISSISQUOI RIVER NEAR RICHFORD, VT.

Location.—About 3 miles downstream from Richford, Franklin County, 3 miles below mouth of North Branch and 2 miles above mouth of Trout River.

Drainage area.—445 square miles.

Records available.—May 22, 1909, to December 3, 1910, and June 26, 1911, to September 30, 1917.

Gage.—Gurley graph water-stage recorder in gage house on left bank, about one-fourth mile above highway bridge; chain gage on highway bridge used June 26, 1911, to July 31, 1915. From May 22, 1909, to December 3, 1910, gage was just below plant of the Sweat-Comings Co. in Richford.

Discharge measurements.—Made from highway bridge or by wading.

Channel and control.—Channel deep; banks not subject to overflow; stream bed composed of gravel, boulders, and ledge rock. Control is sharply defined by rock outcrop about 100 feet below gage.

Extremes of discharge.—Maximum stage during year, from water-stage recorder, 11.53 feet at 5 a. m. April 3 (discharge, 8,690 second-feet); minimum stage, from water-stage recorder, 2.77 feet at 6 a. m. September 28 (discharge, 191 second-feet).

1911–1917: Maximum stage recorded, 16.7 feet by chain gage March 26, 1913 (determination of discharge, 10,200 second-feet, from extension of rating curve may be subject to error); minimum stage recorded, 4.15 feet by chain gage, July 14, 1911 (discharge, 8 second-feet).

Ice.—Stage-discharge relation seriously affected by ice; discharge determined from gage heights corrected for backwater by means of current-meter measurements, observer's notes, and weather records.

Regulation.—Considerable daily fluctuation at low stages caused by operation of power plants at Richford.

Accuracy.—Stage-discharge relation changed slightly, presumably when ice went out March 27. Rating curve fairly well defined below 6,000 second-feet. Operation of water-stage recorder satisfactory during the year except for occasional short periods. Daily discharge ascertained by applying to rating table mean daily gage height determined by inspection of recorder sheets; determinations for periods for which no record was obtained, are based on comparison with records of flow of streams in adjacent drainage basins. Results good for periods when water-stage recorder was in operation, and fair for other periods and during the winter.

Discharge measurements of Missisquoi River near Richford, Vt., during the year ending Sept. 30, 1917.

NOTE.—Stage-discharge relation affected by ice from about Dec. 15 to Mar. 27. Discharge computations for this period based on gage heights corrected for effect of ice by means of two discharge measurements, observer's notes, and weather records. Discharge estimated during periods of open water as follows: Oct. 1, Nov. 3, 12–18, Dec. 3–14, Mar. 28–30, May 20–22, June 5, 7–10, July 10, Aug. 6–8.

Monthly discharge of Missisquoi River near Richford, Vt., for the year ending Sept. 30, 1917.

CLYDE RIVER AT WEST DERBY, VT.

LOCATION.—Just below plant of Newport Electric Light Co. at West Derby (Newport), Orleans County; about 1 mile above mouth of river.

DRAINAGE AREA.—150 square miles.

RECORDS AVAILABLE.—May 25, 1909, to September 30, 1917.

GAGES.—Barrett & Lawrence water-stage recorder on right bank used to March 8, 1917, when a Stevens 8-day water-stage recorder was installed; chain gage fastened to tree is used for auxiliary readings; gage heights referred to chain-gage datum.

DISCHARGE MEASUREMENTS.—Made by wading near gage, or from highway bridge half a mile downstream.

CHANNEL AND CONTROL.—Stream bed rough and irregular; covered with boulders and ledge rock; fall of river rapid for some distance below gage.

EXTREMES OF DISCHARGE.—Maximum stage during year, from water-stage recorder, 3.90 feet at 3 a. m. April 25 (discharge, 1,370 second-feet); minimum stage during year from chain gage 1.98 feet at 8.20 a. m. March 20 (discharge, 86 second-feet).

ICE.—Ice covers large boulders below gage during greater part of winter and causes some backwater.

REGULATION.—Flow at ordinary stages fully controlled by two dams at West Derby, but power plant is so operated that fluctuations in stage are not great. Distribution of flow affected also by several dams above West Derby. Seymour Lake and several smaller ponds in the basin afford a large amount of natural storage, but at the present time there is little if any artificial regulation at these ponds.

ACCURACY.—Stage-discharge relation practically permanent except when affected by ice; individual current-meter measurements occasionally plot erratically, probably because of rough measuring section. Rating curve fairly well defined. Operation of water-stage recorder unsatisfactory during a part of the year on account of clock stopping, as indicated in footnote to daily-discharge table. Daily discharge ascertained by applying mean daily gage heights to rating table, using observer's reading of chain gage when recorder was not in operation (chain-gage readings to quarter-tenths twice daily). Records fair.

Discharge measurements of Clyde River at West Derby, Vt., during the year ending Sept. 30, 1917.

INDEX.

STREAM-GAGING STATIONS

AND

PUBLICATIONS RELATING TO WATER RESOURCES

PART IV. ST. LAWRENCE RIVER BASIN

STREAM-GAGING STATIONS AND PUBLICATIONS RELATING TO WATER RESOURCES.

INTRODUCTION.

Investigation of water resources by the United States Geological Survey has consisted in large part of measurements of the volume of flow of streams and studies of the conditions affecting that flow, but it has comprised also investigations of such closely allied subjects as irrigation, water storage, water powers, underground waters, and quality of waters. Most of the results of these investigations have been published in the series of water-supply papers, but some have appeared in the bulletins, professional papers, monographs, and annual reports.

The results of stream-flow measurements are now published annually in 12 parts, each part covering an area whose boundaries coincide with natural drainage features, as indicated below:

Part I. North Atlantic slope basins.
II. South Atlantic slope and eastern Gulf of Mexico basins.
III. Ohio River basin.
IV. St. Lawrence River basin.
V. Upper Mississippi River and Hudson Bay basins.
VI. Missouri River basin.
VII. Lower Mississippi River basin.
VIII. Western Gulf of Mexico basins.
IX. Colorado River basin.
X. Great Basin.
XI. Pacific slope basins in California.
XII. North Pacific slope basins, in three volumes:
A. Pacific slope basins in Washington and upper Columbia River basin.
B. Snake River basin.
C. Lower Columbia River basin and Pacific slope basins in Oregon.

HOW GOVERNMENT REPORTS MAY BE OBTAINED OR CONSULTED.

Water-supply papers and other publications of the United States Geological Survey containing data in regard to the water resources of the United States may be obtained or consulted as indicated below:

1. Copies may be obtained free of charge by applying to the Director of the Geological Survey, Washington, D. C. The edition printed for free distribution is, however, small and is soon exhausted.

2. Copies may be purchased at nominal cost from the Superintendent of Documents, Government Printing Office, Washington, D. C., who will on application furnish list giving prices.

3. Sets of the reports may be consulted in the libraries of the principal cities in the United States.

4. Complete sets are available for consultation in the local offices of the water-resources branch of the Geological Survey, as follows:

Boston, Mass., 2500 Customhouse.
Albany, N. Y., 704 Journal Building.
Atlanta, Ga., Post Office Building.
Chicago, Ill., 1404 Kimball Building.
Madison, Wis., care of Railroad Commission of Wisconsin.
Helena, Mont., Montana National Bank Building.
Denver, Colo., 403 New Post Office Building.
Topeka, Kans., Room 25, Federal Building.
Salt Lake City, Utah, 421 Federal Building
Boise, Idaho, 615 Idaho Building.
Tucson, Ariz., University of Arizona.
Austin, Tex., Capitol Building.
Portland, Oreg., 606 Post Office Building.
Tacoma, Wash., 406 Federal Building.
San Francisco, Calif., 328 Customhouse.
Los Angeles, Calif., 619 Federal Building.
Honolulu, Hawaii, 14 Capitol Building.

A list of the Geological Survey's publications may be obtained by applying to the Director of the United States Geological Survey, Washington, D. C.

STREAM-FLOW REPORTS.

Stream-flow records have been obtained at more than 4,240 points in the United States, and the data obtained have been published in the reports tabulated below:

Stream-flow data in reports of the United States Geological Survey.

[A=Annual Report; B=Bulletin; W=Water-Supply Paper.]

B 131	Descriptions, measurements, gage heights, and ratings	1893 and 1894
16th A, pt. 2	Descriptive information only	
B 140	Descriptions, measurements, gage heights, ratings, and monthly discharge (also many data covering earlier years).	1895.
W 11	Gage heights (also gage heights for earlier years)	1896.
18th A, pt. 4	Descriptions, measurements, ratings, and monthly discharge (also similar data for some earlier years).	1895 and 1896.
W 15	Descriptions, measurements, and gage heights, eastern United States, eastern Mississippi River, and Missouri River above junction with Kansas.	1897.

Stream-flow data in reports of the United States Geological Survey—Continued.

Report.	Character of data.	Year.
W 15	Descriptions, measurements, and gage heights, western Mississippi River below junction of Missouri and Platte, and western United States.	1897.
19th A, pt. 4	Descriptions, measurements, ratings, and monthly discharge (also some long-time records).	1897.
W 27	Measurements, ratings, and gage heights, eastern United States, eastern Mississippi River, and Missouri River.	1898.
W 28	Measurements, ratings, and gage heights, Arkansas River and western United States.	1898.
20th A, pt. 4	Monthly discharge (also for many earlier years)	1898.
W 35 to 39	Descriptions, measurements, gage heights, and ratings	1899.
21st A, pt. 4	Monthly discharge	1899.
W 47 to 52	Descriptions, measurements, gage heights, and ratings	1900.
22d A, pt. 4	Monthly discharge	1900.
W 65, 66	Descriptions, measurements, gage heights, and ratings	1901.
W 75	Monthly discharge	1901.
W 82 to 85	Complete data	1902.
W 97 to 100	do	1903.
W 124 to 135	do	1904.
W 165 to 178	do	1905.
W 201 to 214	do	1906.
W 241 to 252	do	1907–8.
W 261 to 272	do	1909.
W 281 to 292	do	1910.
W 301 to 312	do	1911.
W 321 to 332	do	1912.
W 351 to 362	do	1913.
W 381 to 394	do	1914.
W 401 to 414	do	1915.
W 431 to 444	do	1916.
W 451 to 464	do	1917.

The records at most of the stations discussed in these reports extend over a series of years, and miscellaneous measurements at many points other than regular gaging stations have been made each year. An index of the reports containing records obtained prior to 1904 has been published in Water-Supply Paper 119.

The following table gives, by years and drainage basins, the numbers of the papers on surface-water supply published from 1899 to 1917. The data for any particular station will, as a rule, be found in the reports covering the years during which the station was maintained. For example, data for Machias River at Whitneyville, Me., 1903 to 1917, are published in Water-Supply Papers 97, 124, 165, 201, 241, 261, 281, 301, 321, 351, 381, 401, 431, and 451, which contain records for the New England streams from 1903 to 1917. Results of miscellaneous measurements are published by drainage basins.

94446°—19—WSP 454——9

Numbers of water-supply papers containing results of stream measurements, 1899–1917.

Year.	I	II	III	IV	V	VI	VII	VIII	IX	X	XI	XII North Pacific slope basins.		
	North Atlantic slope (St. John River to York River).	South Atlantic and eastern Gulf of Mexico (James River to the Mississippi).	Ohio River basin.	St. Lawrence River and Great Lakes basins.	Hudson Bay and upper Mississippi River basins.	Missouri River basin.	Lower Mississippi River basin.	Western Gulf of Mexico basins.	Colorado River basin.	Great Basin.	Pacific slope basins in California.	Pacific slope basins in Washington and upper Columbia River.	Snake River basin.	Lower Columbia River and Pacific slope basins in Oregon.

[q] Platte and Kansas rivers.
[r] Great Basin in California, except Truckee and Carson river basins.
[s] Below junction with Gila.
[t] Rogue, Umpqua, and Siletz rivers only.

In these papers and in the following lists the stations are arranged in downstream order. The main stem of any river is determined by measuring or estimating its drainage area—that is, the headwater stream having the largest drainage area is considered the continuation of the main stream, and local changes in name and lake surface are disregarded. All stations from the source to the mouth of the main stem of the river are presented first, and the tributaries in regular order from source to mouth follow, the streams in each tributary basin being listed before those of the next basin below.

The exceptions to this rule occur in the records for Mississippi River, which are given in four parts, as indicated on page III, and in the records for the large lakes, where it is simpler to take up the streams in regular order around the rim of the lake than to cross back and forth over the lake surface.

Part IV. ST. LAWRENCE RIVER BASIN.

PRINCIPAL STREAMS.

The St. Lawrence River basin includes streams which drain into the Great Lakes and St. Lawrence River. The principal streams flowing directly or indirectly into Lake Superior from the United States are St. Louis, Ontonagon, Dead, and Carp rivers; streams flowing into Lake Michigan are Escanaba, Menominee, Peshtigo, Oconto, Fox, St. Joseph, and Grand rivers; into Lake Huron flow Thunder Bay, Au Sable, Rifle, and Saginaw rivers; into Lake Erie flow Huron, Maumee, Sandusky, Black, and Cuyahoga rivers. Streams flowing into Lake Ontario are Genesee, Oswego, Salmon, and Black rivers. The St. Lawrence receives Oswegatchie and Raquette rivers, Richelieu River (the outlet of Lake Champlain), and St. Francis River, whose principal tributary, Clyde River, reaches it through Lake Memphremagog. The streams of this basin drain wholly or in part the States of Illinois, Indiana, Michigan, Minnesota, New York, Ohio, Pennsylvania, Vermont, and Wisconsin.

In addition to the list of gaging stations and annotated list of publications relating specifically to the section, this part contains a similar list of reports that are of general interest in many sections and cover a wide range of hydrologic subjects, and also brief references to reports published by State and other organizations. (See p. XIX.)

GAGING STATIONS.

NOTE.—Dash following a date indicates that station was being maintained September 30, 1917. Period after date indicates discontinuance.

Streams tributary to Lake Superior:
- Brule River at mouth, Minn., 1911.
- Devil Track River at mouth, Minn., 1911.
- Cascade River at mouth, Minn., 1911.
- Poplar River at Lutsen, Minn., 1911–
- Beaver Bay River at Beaver Bay, Minn., 1911–1914.
- St. Louis River near Cloquet, Minn., 1903.
- St. Louis River near Thomson, Minn., 1909–1915.
  - Whiteface River at Meadowlands, Minn., 1909–1912.
  - Whiteface River below Meadowlands, Minn., 1912–
  - Cloquet River at Independence, Minn., 1909–
- Aminicon River near Aminicon Falls, Wis., 1914–1916.
- Brule River near Brule, Wis., 1914–
- Bad River near Odanah, Wis., 1914–
- Ontonagon River near Rockland, Mich., 1903.

Streams tributary to Lake Superior—Continued.
- Sturgeon River near Sidnaw, Mich., 1912–1915.
- Perch River near Sidnaw, Mich., 1912–1915.
- Dead River near Negaunee, Mich., 1902–3.
- Dead River at Forestville, Mich., 1898–1902.
- Carp River near Marquette, Mich., 1902–3.

Streams tributary to Lake Michigan:
- Escanaba River near Escanaba, Mich., 1903–1915.
- Brule River (head of Menominee River) near Florence, Wis., 1914–1916.
- Menominee River near Iron Mountain, Mich., 1902–1914.
- Menominee River at Lower Quinnesec Falls, Wis., 1898–99.
- Menominee River at Koss, Mich., 1902–1909; 1914.
- Menominee River below Koss, Mich., 1913–
  - Iron River near Iron River, Mich., 1900–1905.
  - Pine River near Florence, Wis., 1914–
  - Pike River at Amberg., Wis., 1914–
- Peshtigo River at High Falls, near Crivitz, Wis., 1912–
- Peshtigo River near Crivitz, Wis., 1906–1909.
- Peshtigo River at Crivitz, Wis., 1906.
- Oconto River near Gillett, Wis., 1906–1909; 1914–
- Oconto River at Stiles, Wis., 1906.
- Fox River at Omro, Wis., 1902–3.
- Fox River at Oshkosh, Wis., 1902.
- Fox River at Wrightstown, Wis., 1902–1904.
- Fox River at Rapide Croche dam, Wis., 1896–
  - Wolf River at Keshena, Wis., 1907–1909; 1911–
  - Wolf River at White House Bridge, near Shawano, Wis., 1906–7.
  - Wolf River at Darrows Bridge, near Shawano, Wis., 1906.
  - Wolf River at New London, Wis., 1913–
  - Wolf River at Northport, Wis., 1905.
  - Wolf River at Winneconne, Wis., 1902–3.
    - West Branch of Wolf River at Neopit, Wis., 1911–
    - Little Wolf River at Royalton, Wis., 1914–
    - Little Wolf River near Northport, Wis., 1907–1910.
    - Waupaca River near Weyauwega, Wis., 1916–
  - Fond du Lac River, West Branch (head of Fond du Lac River) at Fond du Lac, Wis., 1903.
  - East Branch of Found du Lac River at Fond du Lac, Wis., 1903.
- Sheboygan River near Sheboygan, Wis., 1916–
- Milwaukee River near Milwaukee, Wis., 1914–
- Little Calumet River at Harvey, Ill., 1916–
- St. Joseph River at Mendon, Mich., 1902–1905.
- St. Joseph River near Buchanan, Mich., 1901–1906.
  - Fawn River at White Pigeon, Mich., 1903–4.
- Kalamazoo River near Allegan, Mich., 1901–1907.
  - Reeds Springs near Albion, Mich., 1904–1906.
- Grand River at North Lansing, Mich., 1901–1906.
- Grand River at Grand Rapids, Mich., 1901–
  - Crockery Creek at Slocums Grove, Mich., 1902–3.
  - Red Cedar River at Agricultural College, Mich., 1902–3.
- Muskegon River at Newaygo, Mich., 1901–1906.
- Manistee River near Sherman, Mich., 1903–1916.
- Boardman River at Traverse City, Mich., 1904.

Streams tributary to Lake Huron:
- Thunder Bay River near Alpena, Mich., 1901–1908.
- Au Sable River near Lovells, Mich., 1908–1914.
- Au Sable River at Bamfield, Mich., 1902–1913.
- Rifle River near Sterling, Mich., 1905–1908.
- Rifle River at Omer, Mich., 1902–3.
- Shiawassee River (head of Saginaw River):
  - Flint River at Flint, Mich., 1903–4.
  - Cass River at Frankenmuth, Mich., 1908–9.
  - Cass River at Bridgeport, Mich., 1908.
  - Tittabawassee River at Freeland, Mich., 1903–1909; 1912–

Streams tributary to Lake Erie:
- Huron River at Dover, Mich., 1904.
- Huron River at Dexter, Mich., 1904–1916.
- Huron River at Barton, Mich., 1914–
- Huron River at Geddes, Mich., 1904–1914.
- Huron River at French Landing, Mich., 1904–5.
- Huron River at Flat Rock, Mich., 1904–
- Maumee River near Sherwood, Ohio, 1903–1906.
- Maumee River near Waterville, Ohio, 1898–1901.
  - St. Marys River at Fort Wayne, Ind., 1905–6.
  - St. Joseph River at Fort Wayne, Ind., 1905–6.
  - Tiffin River near Defiance, Ohio, 1903–1906.
  - Auglaize River near Defiance, Ohio, 1903.
    - Ottawa River at Lima, Ohio, 1902–3.
    - Blanchard River at Ottawa, Ohio, 1902–3.
- Sandusky River near Mexico, Ohio, 1898–1900.
- Sandusky River at Fremont, Ohio, 1898–1901.
- Black River near Elyria, Ohio, 1903–1906.
- Cuyahoga River at Independence, Ohio, 1903–1906.
- Cuyahoga River at Cleveland, Ohio, 1903.
- Cattaraugus Creek at Versailles, N. Y., 1910–

Streams tributary to Lake Ontario:
- Niagara River:
  - Tonawanda Creek:
    - Little Tonawanda Creek near Linden, N. Y., 1912–
- Genesee River at Scio, N. Y., 1916–
- Genesee River at St. Helena, N. Y., 1908–
- Genesee River at Mount Morris, N. Y., 1905–1909.
- Genesee River at Jones Bridge, near Mount Morris, N. Y., 1903–1906; 1908–1913; 1915–
- Genesee River at Rochester, N. Y., 1904–
  - Canaseraga Creek near Dansville, N. Y., 1910–1912; 1915–1917.
  - Canaseraga Creek at Groveland station, N. Y., 1915–
  - Canaserago Creek at Shakers Crossing, N. Y., 1915–
    - Keshequa Creek at Sonyea, N. Y., 1910–1912.
    - Keshequa Creek near Sonyea, N. Y., 1915–1917.
  - Hemlock Lake at Hemlock, N. Y., 1894–1902.
    - Canadice outlet near Hemlock, N. Y., 1903–
    - Honeoye Creek at East Rush, N. Y., 1903–1906.
- Seneca River (head of Oswego River) at Baldwinsville, N. Y., 1898–1908.
- Oswego River at Fulton, N. Y., 1900; 1902.
- Oswego River at Battle Island, above Minetto, N. Y., 1900–1906.

Streams tributary to Lake Ontario—Continued.
- Oswego River at high dam, near Oswego, N. Y., 1897-1901.
  - Seneca Lake at Geneva, N. Y., 1905-6.
  - Cayuga Lake at Ithaca, N. Y., 1905-1908.
    - Fall Creek near Ithaca, N. Y., 1908-9.
  - Owasco Lake outlet near Auburn, N. Y., 1912-
  - Skaneateles Lake at Skaneatleles, N. Y., 1890-91.
  - Skaneateles Lake outlet at Willow Glen, N. Y., 1892-1908.
  - Skaneateles Lake outlet at Jordan, N. Y., 1890-1892.
  - Onondaga Lake outlet at Long Branch, N. Y., 1904.
  - West Branch of Onondago Creek at South Onondaga, N. Y., 1916-
  - Fish Creek, East Branch (through Oneida Lake, head of Oneida River), at Point Rock, N. Y., 1898-99.
  - Oneida River at Brewerton, N. Y., 1899.
  - Oneida River at Oak Orchard, near Euclid, N. Y., 1902-1909.
  - Oneida River at Caughdenoy, N. Y., 1910-1913.
    - Fish Creek:
      - West Branch of Fish Creek at McConnellsville, N. Y., 1898-1901.
      - Oneida Creek at Kenwood, N. Y., 1898-1900.
      - Chittenango Creek at Chittenango, N. Y., 1901-1906.
      - Chittenango Creek at Bridgeport, N. Y., 1898-1901.
- Salmon River at Stillwater Bridge, near Redfield, N. Y., 1911-1913.
- Salmon River near Pulaski, N. Y., 1900-1908; 1910-1914.
  - Orwell Brook near Altmar, N. Y., 1911-1916.
- Black River near Boonville, N. Y., 1911-
- Black River near Felts Mills, N. Y., 1902-1913.
- Black River at Black River, N. Y., 1917-
- Black River at Huntingtonville dam, near Watertown, N. Y., 1897-1901.
  - Forestport feeder near Boonville, N. Y., 1915-
  - Black River canal flowing south near Boonville, N. Y., 1915-
  - Moose River at Moose River, N. Y., 1900-
    - Middle Branch of Moose River at Old Forge, N. Y., 1911-
  - Beaver River at State dam, near Beaver River, N. Y., 1908-
  - Beaver River at Croghan, N. Y., 1901-1903.

Streams tributary to the St. Lawrence:
- Oswegatchie River, East Branch (head of Oswegatchie River), at Newton Falls, N. Y., 1912-
- Oswegatchie River near Heuvelton, N. Y., 1916-
- Oswegatchie River near Ogdensburg, N. Y., 1903-1916.
  - West Branch of Oswegatchie River near Harrisville, N. Y., 1916-
- Raquette River at Raquette Falls, near Coreys, N. Y., 1908-1912.
- Raquette River at Piercefield, N. Y., 1908-
- Raquette River at South Colton, N. Y., 1904.
- Raquette River at Massena Springs, N. Y., 1903-1916.
  - Bog River near Tupper Lake, N. Y., 1908-1912.
- St. Regis River at Brasher Center, N. Y., 1910-
  - Deer River at Brasher Iron Works (railroad station), Ironton, N. Y., 1912-1916.
- Chateaugay River near Chateaugay, N. Y., 1908.
- Richelieu River at Fort Montgomery, N. Y., 1875-
  - Lake Champlain at Burlington, Vt., 1907-
    - Big Chazy River at Moors, N. Y., 1908.
    - Saranac River at Saranac Lake, N. Y., 1902-3.
    - Saranac River near Plattsburg, N. Y., 1903-
    - Ausable River, West Branch, near Newman, N. Y., 1916-

Streams tributary to the St. Lawrence—Continued.
- Richelieu River—Continued.
  - Lake Champlain—Continued.
    - Ausable River at Ausable Forks, N. Y., 1910–
    - Ausable River at Keeseville, N. Y., 1904 and 1908.
    - Boquet River at Willsboro, N. Y., 1904 and 1908.
    - Lake George at Rogers Rock, N. Y., 1913–
    - Lake George outlet at Ticonderoga, N. Y., 1904–5.
    - Poultney River at Fairhaven, Vt., 1908.
      - Mettawee River at Whitehall, N. Y., 1908.
    - Otter Creek at Middlebury, Vt., 1903–1907; 1910–
      - East Creek near Rutland, Vt., 1911–1913.
    - Winooski River above Stevens Branch, near Montpelier, Vt., 1909–1914.
    - Winooski River at Montpelier, Vt., 1909–
    - Winooski River at Richmond, Vt., 1903–1907; 1910.
    - Winooski River near Winooski, Vt., 1903.
      - Worcester Branch of Winooski River at Montpelier, Vt., 1909–1914.
      - Dog River at Northfield, Vt., 1909–
      - Dog River near Montpelier Junction, Vt., 1910.
      - Mad River at Moretown, Vt., 1910.
      - Little River near Waterbury, Vt., 1910.
      - Huntington River at Jonesville, Vt., 1910.
    - Lamoille River at Morrisville, Vt., 1909–10.
    - Lamoille River at Cadys Falls, near Morrisville, Vt., 1913–
    - Lamoille River at Johnson, Vt., 1910–1913.
    - Lamoille River at West Milton, Vt., 1903.
      - Green River at Garfield, Vt., 1915–
    - Missisquoi River at Richford, Vt., 1909–10.
    - Missisquoi River near Richford, Vt., 1911–
    - Missisquoi River at Swanton, Vt., 1903.
- St. Francis River (by way of Lake Memphremagog and Magog River):
  - Clyde River at West Derby, Vt., 1909–

REPORTS ON WATER RESOURCES OF THE ST. LAWRENCE RIVER BASIN.[1]

PUBLICATIONS OF THE UNITED STATES GEOLOGICAL SURVEY.

WATER-SUPPLY PAPERS.

Water-supply papers are distributed free by the Geological Survey as long as its stock lasts. An asterisk (*) indicates that this stock has been exhausted. Many of the papers marked in this way may, however, be purchased from the SUPERINTENDENT OF DOCUMENTS, WASHINGTON, D. C. Water-supply papers are of octavo size.

*21. Wells of Northern Indiana, by Frank Leverett. 1899. 82 pp., 2 pls. (Continued in No. 26.)

Discusses, by counties, the glacial deposits and the sources of well water; gives many well sections.

*24. Water resources of the State of New York, Part I, by G. W. Rafter. 1899. 99 pp., 13 pls. 15c.

*25. Water resources of the State of New York, Part II, by G. W. Rafter. 1899. 100 pp., 12 pls. 15c.

No. 24 contains descriptions of the principal rivers of New York and their more important tributaries and data on temperature, precipitation, evaporation, and stream flow.

No. 25 contains discussion of water-storage projects on Genesee and Hudson Rivers, power development at Niagara Falls, descriptions and early history of State canals, and a chapter on the use and value of the water powers of the streams and canals; also brief discussion of the water yield of sand areas of Long Island.

*26. Wells of southern Indiana (continuation of No. 21), by Frank Leverett. 1899. 64 pp. 5c.

Discusses, by counties, the glacial deposits and the sources of well water; contains many well sections.

30. Water resources of the Lower Peninsula of Michigan, by A. C. Lane. 1899. 97 pp. 7 pls.

Describes lake and river transportation and navigation, water powers and domestic water supplies; discusses climate, topography, geology, and well waters; compares quality and quantity of waters.

*31. Lower Michigan mineral waters, by A. C. Lane. 1899. 97 pp., 4 pls. 10c.

Treats of economic value of mineral waters and discussion and classification of analyses; contains analyses of waters of Lake Superior and of smaller lakes and rivers and of well waters from various geologic formations; also sanitary condition of drinking waters.

*57. Preliminary list of deep borings in the United States, Part I (Alabama-Montana), by N. H. Darton. 1902. 60 pp. (See No. 149.) 5c.

*61. Preliminary list of deep borings in the United States, Part II (Nebraska-Wyoming), by N. H. Darton. 1902. 67 pp. 5c.

Nos. 57 to 61 contain information as to depth, diameter, yield, and head of water in borings more than 400 feet deep; under head "Remarks" give information concerning temperature, quality of water, purposes of boring, etc. The lists are arranged by States, and the States are arranged alphabetically. A second, revised, edition was published in 1905 as Water-Supply Paper 149 (q. v.)

XIV.

91. The natural features and economic development of the Sandusky, Maumee, Muskingum, and Miami drainage areas in Ohio, by B. H. and M. S. Flynn. 1904. 130 pp. 10c.

Describes the topography, geology, and soils of the areas, and discusses stream flow, dams, water powers, and public water supplies.

---

[1] For stream-measurement reports, see tables on pp. IV, V, VI.

102. Contributions to the hydrology of eastern United States, 1903; M. L. Fuller, geologist in charge. 1904. 522 pp. 30c.

Contains brief reports on wells and springs of Minnesota and of lower Michigan. The report comprises tabulated well records giving information as to location, owner, depth yield, head, etc., supplemented by notes as to elevation above sea, materials penetrated, temperature, use and quality; many miscellaneous analyses.

*108. A review of the laws forbidding pollution of inland waters in the United States, by E. B. Goodell. 1904. 120 pp. Superseded by 152.

Cites statutory restrictions of water pollution.

110. Contributions to the hydrology of eastern United States, 1904; M. L. Fuller, geologist in charge. 1905. 211 pp., 5 pls. 10c.

Contains:

Water resources of the Watkins Glen quadrangle, New York, by Ralph S. Tarr; pp. 134-140. Discusses the use of the surface and underground waters for municipal supplies and their quality as indicated by examination of Sixmile and Fall creeks, and sanitary analyses of well water at Ithaca.

New artesian water supply at Ithaca, New York, by F. L. Whitney, pp. 55-64.

*114. Underground waters of eastern United States; M. L. Fuller, geologist in charge. 1905. 285 pp., 18 pls. 25c.

Contains brief reports as follows:

Minnesota, by C. W. Hall; Wisconsin district, by Alfred R. Schultz; Lower Michigan; Illinois, by Frank Leverett; Indiana, by Frank Leverett; New York, by F. B. Weeks; Ohio, by Frank Leverett.

Each of these reports describes briefly the topography of the area, the relation of the geology to the water supplies, and gives list of pertinent publications; lists also principal mineral springs.

121. Preliminary report on the pollution of Lake Champlain, by M. O. Leighton. 1905. 119 pp., 13 pls. 20c.

Describes the lake and principal inflowing streams and discusses the characteristics of the water and the wastes resulting from the manufacturing processes by which the waters are polluted. Discusses also the effect of mill waste on algæ, bacteria, and fish.

*122. Relation of the law to underground waters, by D. W. Johnson. 1905. 55 pp. 5c.

Cites legislative acts relating to ground waters in Michigan and Wisconsin.

144. The normal distribution of chlorine in the natural waters of New York and New England, by D. D. Jackson. 1905. 31 pp., 5 pls. 10c.

Discusses common salt in coast and inland waters, salt as an index to pollution of streams and wells, the solutions and methods used in chlorine determinations, and the use of the normal chlorine map; gives charts and tables for chlorine in the New England States and New York.

145. Contributions to the hydrology of eastern United States, 1905; M. L. Fuller, geologist in charge. 1905. 220 pp., 6 pls. 10c.

Contains three brief reports pertaining chiefly to areas in the St. Lawrence River basin:

Two unusual types of artesian flow, by Myron L. Fuller. Describes (1) artesian flows from uniform, unconfined sand on Long Island, N. Y., and in Michigan; and (2) flow from jointed upper portion of limestone and other rocks in southeastern Michigan.

Water resources of the Catatonk area, New York, by E. M. Kindle. Describes topography and geology of areas southeast of Finger Lake region, New York, including part of city of Ithaca; discusses briefly the artesian wells of Ithaca, the quality of the spring water at several small towns, and of the streams used for municipal supplies and for power.

A ground-water problem in southeastern Michigan, by Myron L. Fuller. Discusses causes of failure of wells in certain areas in southeastern Michigan in 1904 and the application of the conclusions to other regions.

147. Destructive floods in the United States in 1904, by E. C. Murphy and others. 1905. 206 pp., 18 pls. 15c.

Describes flood on Grand River, Mich. (from report of R. E. Horton), discussing streams precipitation, and temperature, discharge, damage, and prevention of future damage.

*149. Preliminary list of deep borings in the United States, second edition, with additions, by N. H. Darton. 1905. 175 pp. 10c.

Gives by States (and within the States by counties) the location, depth, diameter, yield, height of water, and other features of wells 400 feet or more in depth; includes all wells listed in Water-Supply Papers 57 to 61; mentions also principal publications relating to deep borings.

*152. A review of the laws forbidding pollution of inland waters in the United States (second edition), by E. B. Goodell. 1905. 149 pp. 10c.

Cites statutory restrictions of water pollution in Illinois, Indiana, Michigan, Minnesota, New York, Ohio, Pennsylvania, Vermont, and Wisconsin.

*156. Water powers of northern Wisconsin, by L. S. Smith. 1906. 145 pp., 5 pls. 25c.

Describes, by river systems, the drainage, geology, topography, rainfall, and run-off, water powers and dams.

*160. Underground-water papers, 1906; M. L. Fuller, geologist in charge. 1906. 104 pp., 1 pl.

Contains brief report entitled Flowing well districts in the eastern part of the northern peninsula of Michigan, by Frank Leverett.

*162. Destructive floods in the United States in 1905, with a discussion of flood discharge and frequency and an index to flood literature, by E. C. Murphy and others. 1906. 105 pp., 4 pls. 15c.

Contains accounts of floods on Sixmile Creek and Cayuga Inlet, N. Y. (in 1857, 1901, and 1905), and on Grand River, Mich., and estimate of flood discharge and frequency for Genesee River; gives index to literature on floods in American streams.

*182. Flowing wells and municipal water supplies in the southern portion of the southern peninsula of Michigan, by Frank Leverett and others. 1906. 292 pp., 5 pls. 50c.

*183. Flowing wells and municipal water supplies in the middle and northern portions of the southern peninsula of Michigan, by Frank Leverett and others. 1907. 393 pp., 5 pls. 50c.

Nos. 182 and 183 describe in general the geographic features, water-bearing formations, drainage, quality of water, and subterranean-water temperature, and give details concerning water supplies by counties. The report contains many analyses.

*193. The quality of surface waters in Minnesota, by R. B. Dole and F. F. Wesbrook, 1907. 171 pp., 7 pls. 25c.

Describes by river basins the topography, geology, and soils, the industrial and municipal pollution of the streams, and gives notes on the municipalities; contains many analyses.

*194. Pollution of Illinois and Mississippi rivers by Chicago sewage (a digest of the testimony taken in the case of the State of Missouri *v.* the State of Illinois and the Sanitary District of Chicago), by M. O. Leighton. 1907. 369 pp., 2 pls.

Scope indicated by amplification of title.

236. The quality of surface water in the United States: Part I, Analyses of waters east of the one hundredth meridian, by R. B. Dole. 1909. 123 pp. 10c.

Describes collection of samples, method of examination, preparation of solutions, accuracy of estimates, and expression of analytical results; gives results of analyses of waters of Lake Superior and Lake Michigan, Kalamazoo and Grand rivers, Lake Huron, Lake Erie, Maumee River and St. Lawrence and Oswegatchie rivers.

239. The quality of the surface waters of Illinois, by W. D. Collins. 1910. 94 pp., 3 pls. 10c.

Discusses the natural and economic features that determine the character of the streams describes the larger drainage basins and the methods of collecting and analyzing the samples of water, and discusses each river in detail with reference to its source, course, and quality of water; includes short chapters on municipal supplies and industrial uses.

254. The underground waters of north-central Indiana, by S. R. Capps, with a chapter on the chemical character of the waters, by R. B. Dole. 1910. 279 pp., 7 pls. 40c.

Describes relief, drainage, vegetation, soils and crops, industrial development, geologic formations; sources, movements, occurrence, and volume of ground water; methods of well construction and lifting devices; discusses in detail, for each county, surface features and drainage, geology, and ground water, city, village, and rural supplies, and gives record of wells and analyses of water. Discusses also, under chemical character, methods of analyses and expression of results, mineral constituents, effects of the constituents on waters for domestic, industrial, and medicinal uses, methods of purification and chemical composition; many analyses and field assays.

364. Water analyses fron the laboratory of the United States Geological Survey, tabulated by F. W. Clarke, chief chemist. 1914. 40 pp. 5c.

Contains analyses of water from Caledonia Spring, New York, and from the Quincy mine, Mich.

417. Profile surveys of rivers in Wisconsin, prepared under the direction of W. H. Herron, acting chief geographer. 1917. 16 pp., 32 pls. 45c.

Contains brief description of general features of drainage of Wisconsin and of the rivers surveyed, but consists chiefly of maps showing "not only the outlines of the river banks, the islands, the positions of rapids, falls, shoals, and existing dams, and the crossings of all ferries and roads, but the contours of banks to an elevation high enough to indicate the possibility of using the stream."

ANNUAL REPORTS.

Each of the papers contained in the annual reports was also issued in separate form.

Annual reports are distributed free by the Geological Survey as long as its stock lasts. An asterisk (*) indicates that this stock has been exhausted. Many of the papers so marked, however, may be purchased from the SUPERINTENDENT OF DOCUMENTS, WASHINGTON, D. C.

Annual reports 1 to 26 are royal octavo; later reports are octavo.

Fourteenth Annual Report of the United States Geological Survey, 1892–93, J. W. Powell, Director. 1893. (Pt. II, 1894.) 2 parts. *Pt. II. Accompanying papers, xx, 597 pp., 73 pls. $2.10. Contains:

*The potable waters of eastern United States, by W. J. McGee, pp. 1 to 47. Discusses cistern water, stream waters, and ground waters, including mineral springs and artesian wells.

Seventeenth Annual Report of the United States Geological Survey, 1895–96, Charles D. Walcott, Director. 1896. 3 parts in 4 vols. * Pt. II. Economic geology and hydrography, xxv, 864 pp., 113 pls. $2.35. Contains:

*The water resources of Illinois, by Frank Leverett, pp. 695–849, pls. 106–113. Describes the physical features of the State, and the drainage basins, including Illinois, Des Plaines, Kankakee, Fox, Illinois-Vermilion, Spoon, Mackinaw, and Sangamon rivers, Macoupin Creek, Rock River, tributaries of the Mississippi in western Illinois, Kaskaskia, Big Muddy, and tributaries of the Wabash; discusses the rainfall and run-off, navigable waters and water powers, the wells supplying water for rural districts, and artesian wells :contains tabulated artesian well data and water analyses.

Eighteenth Annual Report, United States Geological Survey, 1896–97, Charles D. Walcott, Director. 1897. 5 parts in 6 volumes. *Pt. IV, Hydrography, x, 756 pp., 102 pls. $1.75. Contains:

*The water resources of Indiana and Ohio, by Frank Leverett, pp. 419–560, pls. 33–37. Describes Wabash, Whitewater, Great Miami, Little Miami, Scioto, Hocking, Muskingum, and Beaver rivers and lesser tributaries of the Ohio in Indiana and Ohio, the streams discharging into Lake Erie and Lake Michigan, and streams flowing to the Upper Mississippi through the Illinois; discusses shallow and drift wells, the flowing wells from the drift and deeper artesian wells, and gives records of wells at many of the cities; describes the mineral springs and gives analyses of the waters; contains also tabulated lists of cities using surface waters for water works, and of cities and villages using shallow and deep well waters; discusses the source and quality of the city and village supplies, and gives precipitation tables for various points.

Nineteenth Annual Report of the United States Geological Survey, 1897–98, Charles D. Walcott, Director. 1898. (Pts. II, III, and V, 1899.) 6 parts in 7 volumes and separate case for maps with Pt. V. *Pt. IV. Hydrography. $1.85. Contains:

*The rock waters of Ohio, by Edward Orton, pp. 633-717, pls. 71-73. Describes the principal geologic formations of Ohio and the waters from the different strata; discusses the flowing wells at various points and the artesian wells of the deep preglacial channels in Allen, Auglaize and Mercer counties; discusses city and village supplies; gives analyses of waters from various formations.

MONOGRAPHS.

Monographs are of quarto size. They are not distributed free, but may be obtained from the Geological Survey or from the Superintendent of Documents at the prices given. An asterisk (*) indicates that the Survey's stock of the paper is exhausted. (See Finding lists, pp. 89, 118.)

XLI. Glacial formations and drainage features of the Erie and Ohio basins, by Frank Leverett. 1902. 802 pp., 26 pls. $1.75.

Treats of an area extending westward from Genesee Valley in New York across northwestern Pennsylvania and Ohio, central and southern Indiana, and southward from Lakes Ontario and Erie to Allegheny and Ohio rivers.

BULLETINS.

An asterisk (*) indicates that the Geological Survey's stock of paper is exhausted. Many of the papers so marked may be purchased from the SUPERINTENDENT OF DOCUMENTS, WASHINGTON, D. C.

*264. Record of deep-well drilling for 1904, by M. L. Fuller, E. F. Lines, and A. C. Veatch. 1905. 106 pp. 10c.

Discusses the importance of accurate well records to the driller, to owners of oil, gas, and water wells, and to the geologist; describes the general methods of work; gives tabulated records of wells in Illinois, Indiana, Michigan, Minnesota, New York, Ohio, Pennsylvania, and Wisconsin, and detailed records of wells in Onondaga County, N. Y., and Hancock and Wood counties, Ohio. These wells were selected because they give definite stratigraphic information.

*298. Record of deep-well drilling for 1905, by M. L. Fuller and Samuel Sanford. 1906. 299 pp. 25c.

Gives an account of progress in the collection of well records and samples; contains tabulated records of wells in Illinois, Indiana, Michigan, Minnesota, New York, Ohio, Pennsylvania, Vermont, and Wisconsin, and detailed records of wells in Cook County, Ill.; Erie County, N. Y.; Ottawa, Sandusky, and Summit counties, Ohio; and Manitowoc County, Wis. The wells of which detailed sections are given were selected because they afford valuable stratigraphic information.

GEOLOGIC FOLIOS.

Under the plan adopted for the preparation of a geologic map of the United States the entire area is divided into small quadrangles, bounded by certain meridians and parallels, and these quadrangles, which number several thousand, are separately surveyed and mapped.[1] The unit of survey is also the unit of publication, and the maps and description of each quadrangle are issued in the form of a folio. When all the folios are completed they will constitute the Geologic Atlas of the United States.

A folio is designated by the name of the principal town or of a prominent natural feature within the quadrangle. Each folio includes maps showing the topography, geology, underground structure, and mineral deposits of the area mapped and several pages of descriptive text. The text explains the maps and describes the topographic and geologic features of the country and its mineral products. The topographic map shows roads, railroads, waterways, and, by contour lines, the shapes of the hills and valleys and the height above sea level of all points in the quadrangle. The areal-geology map shows the distribution of the various rocks at the surface. The structural-geology map shows the relations of the rocks to one another underground. The economic-geology map indicates the location of mineral deposits that are commercially valuable. The artesian-water map shows the depth of underground-water horizens. Economic-geology and artesian-water maps are included in folios if the conditions in the areas mapped warrant their publication. The folios are of special interest to students of geography and geology and are valuable as guides in the development and utilization of mineral resources.

Folios 1 to 163, inclusive, are published in only one form (18 by 22 inches), called the library edition. Some of the folios that bear numbers higher than 163 are published also in an octavo edition (6 by 9 inches). Owing to a fire in the Geological Survey building May 18, 1913, the stock of geologic folios was more or less damaged by fire and water, but 80 or 90 per cent of the folios are usable. They will be sold at the uniform price of 5 cents each, with no reduction for wholesale orders. This rate applies to folios in stock from 1 to 184, inclusive (except reprints), also to the library edition of folio 186. The library edition of Folios 185, 187, and higher numbers sells for 25 cents a copy, except that some folios which contain an unusually large amount of matter sell at higher prices. The octavo edition of Folio 185 and higher numbers sell for 50 cents a copy, except Folio 193, which sells for 75 cents a copy. A discount of 40 per cent is allowed on an order for folios or for folios together with topographic maps amounting to $5 or more at the retail rate.

[1] Index maps showing areas in the St. Lawrence basin covered by topographic maps and by geologic folios will be mailed on receipt of request addressed to the director U. S. Geological Survey, Washington, D. C.

All the folios contain descriptions of the drainage of the quadrangles. The folios in the following list contain also brief discussions of the underground waters in connection with the economic resources of the areas and more or less information concerning the utilization of the water resources.

An asterisk (*) indicates that the stock of the folio is exhausted.

*81. Chicago, Illinois-Indiana.

Describes an area embracing not only the immediate site of the city but adjacent parts of Cook, Dupage, and Will counties, Ill.; gives an account of the water power, discusses the quality of the waters, and gives analyses of waters from artesian wells; gives also a list of papers relating to the geology and paleontology of the area.

*140. Milwaukee special, Wisconsin, 5c.

Gives analyses of spring waters and of artesian water in Milwaukee; also tabulated data concerning wells.

155. Ann Arbor, Mich. 25c.

Discusses the present lakes, the lakes of the glacial period, and under "Economic geology," the water resources, including the use of the rivers for power and of the underground waters, shallow and artesian, for city and village supplies; discusses the quality of the waters, and gives details by townships.

*169. Watkins Glen-Catatonk, New York.

Includes discussion of water supply at Ithaca.

190. Niagara, N. Y. 50c. either edition.

Gives analyses of mineral water from well at Akron; discusses briefly the municipal supplies of Buffalo, Niagara Falls, Tonawanda, La Salle, and Youngstown, and the use of Niagara River for power development.

205. Detroit, Mich. 50c. either edition.

Discusses surface and ground waters; gives mineral analyses of water from Lake Huron, from rivers near Detroit, and from salt wells.

MISCELLANEOUS REPORTS.

Other Federal bureaus and State and other organizations have from time to time published reports relating to the water resources of the various sections of the country. Notable among those pertaining to the St. Lawrence River basin are the reports of the Chief of Engineers, United States Army, the State Geological Survey of Illinois, the Illinois Water-Supply Commission, the Rivers and Lakes Commission of Illinois, the New York State Conservation Commission and State Water-Supply Commission, and the water-power report of the Tenth Census (vol. 16). The following reports deserve special mention:

The mineral content of Illinois waters, by Edward Bartow, J. A. Udden, S. W. Parr, and George T. Palmer: Illinois State Geol. Survey Bull. 10, 1909.

Chemical and biological survey of waters of Illinois, by Edward Bartow: Univ. Illinois Pubs. 3, 6, 7, 1906–1909.

Chemical survey of the waters of Illinois, report for the years 1897–1902, by A. W. Palmer, with report on geology of Illinois as related to its water supply, by Charles W. Rolfe: Univ. Illinois Pub.

Diversion of the waters of the Great Lakes by way of the Sanitary and Ship canal of Chicago: A brief of the facts and issues, by Lyman E. Cooley, Chicago, 1913.

The State of Missouri *v.* the State of Illinois and the Sanitary district of Chicago, before Frank S. Bright, commissioner of the Supreme Court of the United States, 1904.

The mineral waters of Indiana, their location, origin, and character, by W. S. Blatchley: Indiana Dept. Geology and Nat. Res. Twenty-sixth Ann. Rept., 1901.

*64. Accuracy of stream measurements, by E. C. Murphy. 1902. 99 pp., 4 pls. (See No. 95.) 10c.

Describes methods of measuring velocity of water and of measuring and computing stream flow and compares results obtained with the different instruments and methods; describes also experiments and results at the Cornell University hydraulic laboratory. A second, enlarged, edition published as Water-Supply Paper 95.

*67. The motions of underground waters, by C. S. Slichter. 1902. 106 pp., 8 pls. 15c.

Discusses origin, depth, and amount of underground waters; permeability of rocks and porosity of soils; causes, rates, and laws of motion of underground water; surface and deep zones of flow and recovery of waters by open wells and artesian and deep wells; treats of the shape and position of the water table; gives simple methods of measuring yield of flowing well; describes artesian wells at Savannah, Ga.

72. Sewage pollution in the metropolitan area near New York City and its effect on inland-water resources, by M. O. Leighton. 1902. 75 pp., 8 pls. 10c.

Defines "normal" and "polluted" waters and discusses the damage resulting from pollution.

79. Normal and polluted waters in northeastern United States, by M. O. Leighton. 1903. 192 pp. 10c.

Defines essential qualities of water for various uses, the impurities in rain, surface, and underground waters, the meaning and importance of sanitary analyses, and the principal sources of pollution; chiefly, "a review of the more readily available records" of examination of water supplies derived from streams in the Merrimack, Connecticut, Housatonic, Delaware, and Ohio River basins; contains many analyses.

*80. The relation of rainfall to run-off, by G. W. Rafter. 1903. 104 pp. 10c.

Treats of measurements of rainfall and laws and measurements of stream flow; gives rainfall, run-off, and evaporation formulas; discusses effect of forests on rainfall and run-off.

87. Irrigation in India (second edition), by H. M. Wilson. 1903. 238 pp., 27 pls. 25c.

First edition was published in Part II of the Twelfth Annual Report.

93. Proceedings of first conference of engineers of the Reclamation Service, with accompanying papers, compiled by F. H. Newell, chief engineer. 1904. 361 pp. 25c.

Contains, in addition to an account of the organization of the hydrographic [water-resources] branch of the United States Geological Survey and the reports of the conference, the following papers of more or less general interest:

Limits of an irrigation project, by D. W. Ross.
Relation of Federal and State laws to irrigation, by Morris Bien.
Electrical transmission of power for pumping, by H. A. Storrs.
Correct design and stability of high masonry dams, by Geo. Y. Wisner.
Irrigation surveys and the use of the plane table, by J. B. Lippincott.
The use of alkaline waters for irrigation, by Thomas A. Means.

*94. Hydrographic manual of the United States Geological Survey, prepared by E. C. Murphy, J. C. Hoyt, and G. B. Hollister. 1904. 76 pp., 3 pls. 10c.

Gives instructions for field and office work relating to measurements of stream flow by current meters. See also No. 95.

*95. Accuracy of stream measurements (second, enlarged edition), by E. C. Murphy. 1904. 169 pp., 6 pls.

Describes methods of measuring and computing stream flow and compares results derived from different instruments and methods. See also No. 94.

*103. A review of the laws forbidding pollution of inland waters in the United States, by E. B. Goodell. 1904. 120 pp. (See No. 152.)

Explains the legal principles under which antipollution statutes become operative, quotes court decisions to show authority for various deductions, and classifies according to scope the statutes enacted in the different States.

110. Contributions to the hydrology of eastern United States, 1904; M. L. Fuller, geologist in charge. 1905. 211 pp., 5 pls. 10c.

Contains the following reports of general interest. The scope of each paper is indicated by its title.

Description of underflow meter used in measuring the velocity and direction of underground water, by Charles S. Slichter.

The California or "stovepipe" method of well construction, by Charles S. Slichter.

Approximate methods of measuring the yield of flowing wells, by Charles S. Slichter.

Corrections necessary in accurate determinations of flow from vertical well casings, from notes furnished by A. N. Talbot.

Experiment relating to problems of well contamination at Quitman, Ga., by S. W. McCallie.

Notes on the hydrology of Cuba, by M. L. Fuller.

113. The disposal of strawboard and oil-well wastes, by R. L. Sackett and Isaiah Bowman. 1905. 52 pp., 4 pls. 5c.

The first paper discusses the pollution of streams by sewage and by trade wastes, describes the manufacture of strawboard, and gives results of various experiments in disposing of the waste. The second paper describes briefly the topography, drainage, and geology of the region about Marion, Ind., the contamination of rock wells and of streams by waste oil and brine.

*114. Undergound waters of eastern United States; M. L. Fuller, geologist in charge. 1905. 285 pp., 18 pls. 25c.

Contains report on "Occurrence of underground waters," by M. L. Fuller, discussing sources, amount, and temperature of waters, permeability and storage capacity of rocks, water-bearing formations, recovery of water by springs, wells, and pumps, essential conditions of artesian flows, and general conditions affecting underground waters in eastern United States.

119. Index to the hydrographic progress reports of the United States Geological Survey, 1888 to 1903, by J. C. Hoyt and B. D. Wood. 1905. 253 pp. 15c.

Scope indicated by title.

120. Bibliographic review and index of papers relating to underground waters published by the United States Geological Survey, 1879–1904, by M. L. Fuller, 1905. 128 pp. 10c.

Scope indicated by title.

*122. Relation of the law to underground waters, by D. W. Johnson. 1905. 55 pp. 5c.

Defines and classifies underground waters, gives common-law rules relating to their use, and cites State legislative acts affecting them.

140. Field measurements of the rate of movement of underground waters, by C. S. Slichter. 1905. 122 pp., 15 pls. 15c.

Discusses the capacity of sand to transmit water, describes measurements of underflow in Rio Hondo, San Gabriel, and Mohave River valleys, Cal., and on Long Island, N. Y., gives results of tests of wells and pumping plants, and describes stovepipe method of well construction.

143. Experiments on steel-concrete pipes on a working scale, by J. H. Quinton. 1905. 61 pp., 4 pls. 5c.

Scope indicated by title.

145. Contributions to the hydrology of eastern United States, 1905; M. L. Fuller, geologist in charge. 1905. 220 pp., 6 pls. 10c.

Contains brief reports of general interest as follows:

Drainage of ponds into drilled wells, by Robert E. Horton. Discusses efficiency, cost, and capacity of drainage wells, and gives statistics of such wells in southern Michigan.

Construction of so-called fountain and geyser springs, by Myron L. Fuller.

A convenient gage for determining low artesian heads, by Myron L. Fuller.

146. Proceedings of second conference of engineers of the Reclamation Service, with accompanying papers, compiled by F. H. Newell, chief engineer. 1905. 267 pp. 15c.

Contains brief account of the organization of the hydrographic [water-resources] branch and the Reclamation Service, reports of conferences and committees, circulars of instruction, and many brief reports on subjects closely related to reclamation, and a bibliography of technical papers by members of the service. Of the papers read at the conference those listed below (scope indicated by title) are of more or less general interest:

Proposed State code of water laws, by Morris Bien.
Power engineering applied to irrigation problems, by O. H. Ensign.
Estimates on tunneling in irrigation projects, by A. L. Fellows.
Collection of stream-gaging data, by N. C. Grover.
Diamond-drill methods, by G. A. Hammond.
Mean-velocity and area curves, by F. W. Hanna.
Importance of general hydrographic data concerning basins of streams gaged, by R. E. Horton.
Effect of aquatic vegetation on stream flow, by R. E. Horton.
Sanitary regulations governing construction camps, by M. O. Leighton.
Necessity of draining irrigated land, by Thos. H. Means.
Alkali soils, by Thos. H. Means.
Cost of stream-gaging work, by E. C. Murphy.
Equipment of a cable gaging station, by E. C. Murphy.
Silting of reservoirs, by W. M. Reed.
Farm-unit classification, by D. W. Ross.
Cost of power for pumping irrigating water, by H. A. Storrs.
Records of flow at current-meter gaging stations during the frozen season, by F. H. Tillinghast.

147. Destructive floods in the United States in 1904, by E. C. Murphy and others. 1905. 206 pp., 18 pls. 15c.

Contains a brief account of "A method of computing cross-section area of waterways," including formulas for maximum discharge and areas of cross section.

*149. Preliminary list of deep borings in the United States, second edition, with additions, by N. H. Darton. 1905. 175 pp. 10c.

Gives by States (and within the States by counties), location, depth, diameter, yield, height of water, and other available information, concerning wells 400 feet or more in depth; includes all wells listed in Water-Supply Papers 57 to 61; mentions also principal publications relating to deep borings.

*150. Weir experiments, coefficients, and formulas, by R. E. Horton. 1906. 189 pp., 38 pls. (See Water-Supply Paper 200.) 15c.

Scope indicated by title.

151. Field assay of water, by M. O. Leighton. 1905. 77 pp., 4 pls.

Discusses methods, instruments, and reagents used in determining turbidity, color, iron, chlorides, and hardness in connection with the studies of the quality of water in various parts of the United States.

*152. A review of the laws forbidding pollution of inland waters in the United States (second edition), by E. B. Goodell. 1905. 149 pp. 10c.

Scope indicated by title.

*160. Underground-water papers, 1906; M. L. Fuller, geologist in charge. 1906. 104 pp., 1 pl.

Gives account of work in 1905; lists of publications relating to underground waters, and contains the following brief reports of general interest:

Significance of the term "artesian," by Myron L. Fuller.
Representation of wells and springs on maps, by Myron L. Fuller.
Total amount of free water in the earth's crust, by Myron L. Fuller.
Use of fluorescein in the study of underground waters, by R. B. Dole.
Problems of water contamination, by Isaiah Bowman.
Instances of improvement of water in wells, by Myron L. Fuller.

*162. Destructive floods in the United States in 1905, with a discussion of flood discharge and frequency and an index to flood literature, by E. C. Murphy and others. 1906. 105 pp., 4 pls. 15c.

*163. Bibliographic review and index of underground-water literature published in the United States in 1905, by M. L. Fuller, F. G. Clapp, and B. L. Johnson. 1906. 130 pp. 15c.

Scope indicated by title.

*179. Prevention of stream pollution by distillery refuse, based on investigations at Lynchburg, Ohio, by Herman Stabler. 1906. 34 pp., 1 pl. 10c.

Describes grain distillation, treatment of slop, sources, character, and effects of effluents on streams; discusses filtration, precipitation, fermentation, and evaporation methods of disposal of wastes without pollution.

*180. Turbine water wheel tests and power tables, by R. E. Horton. 1906. 134 pp. 2 pls. 20c.

Scope indicated by title.

*185. Investigations on the purification of Boston sewage, by C. E. A. Winslow and E. B. Phelps. 1906. 163 pp. 25c.

Discusses composition, disposal, purification, and treatment of sewages and recent tendencies in sewage-disposal practice in England, Germany, and the United States; describes character of crude sewage at Boston, removal of suspended matter, treatment in septic tanks, and purification in intermittent sand filtration and coarse material; gives bibliography.

*186. Stream pollution by acid-iron wastes, a report based on investigations made at Shelby, Ohio, by Herman Stabler. 1906. 36 pp., 1 pl.

Gives history of pollution by acid-iron wastes at Shelby, Ohio, and resulting litigation; discusses effect of acid-iron liquors on sewage purification processes, recovery of copperas from acid iron wastes, and other processes for removal of pickling liquor.

*187. Determination of stream flow during the frozen season, by H. K. Barrows and R. E. Horton. 1907. 93 pp., 1 pl. 15c.

Scope indicated by title.

*189. The prevention of stream pollution by strawboard waste, by E. B. Phelps. 1906. 29 pp., 2 pls.

Describes manufacture of strawboard, present and proposed methods of disposal of waste liquors, laboratory investigations of precipitation and sedimentation, and field studies of amount and character of water used, raw material and finished product, and mechanical filtration.

*194. Pollution of Illinois and Mississippi rivers by Chicago sewage (a digest of the testimony taken in the case of The State of Missouri *v.* The State of Illinois and the Sanitary District of Chicago), by M. O. Leighton. 1907. 369 pp., 2 pls.

Scope indicated by amplification of title.

*200. Weir experiments, coefficients, and formulas (revision of paper No. 150), by R. E. Horton. 1907. 195 pp., 38 pls. 35c.

Scope indicated by title.

*226. The pollution of streams by sulphite-pulp waste, a study of possible remedies, by E. B. Phelps. 1909. 37 pp., 1 pl. 10c.

Describes the manufacture of sulphite pulp, the waste liquors, and the experimental work leading to suggestions as to methods of preventing stream pollution.

*229. The disinfection of sewage and sewage filter effluents, with a chapter on the putrescibility and stability of sewage effluents, by E. B. Phelps. 1909. 91 pp., 1 pl. 15c.

Scope indicated by title.

*234. Papers on the conservation of water resources. 1909. 96 pp., 2 pls. 15c.

Contains the following papers, whose scope is indicated by their titles: Distribution of rainfall, by Henry Gannett; Floods, by M. O. Leighton; Developed water powers, compiled under the direction of W. M. Steuart, with discussion by M. O. Leighton; Undeveloped water powers, by M. O. Leighton; Irrigation, by F. H. Newell; Underground waters, by W. C. Mendenhall; Denudation, by R. B. Dole and Herman Stabler; Control of catchment areas, by H. N. Parker.

*235. The purification of some textile and other factory wastes, by Herman Stabler and G. H. Pratt. 1909. 76 pp. 10c.

Discusses waste waters from wool scouring, bleaching and dyeing cotton yarn, bleaching cotton piece goods, and manufacture of oleomargarine, fertilizer, and glue.

236. The quality of surface waters in the United States: Part I, Analyses of waters east of the one hundredth meridian, by R. B. Dole. 1909. 123 pp. 10c.

Describes collection of samples, method of examination, preparation of solutions, accuracy of estimates, and expression of analytical results.

238. The public utility of water powers and their governmental regulation, by René Tavernier and M. O. Leighton. 1910. 161 pp. 15c.

Discusses hydraulic power and irrigation, French, Italian, and Swiss legislation relative to the development of water powers, and laws proposed in the French Parliament; reviews work of bureau of hydraulics and agricultural improvement and the French department of agriculture, and gives résumé of Federal and State water-power legislation in the United States.

*255. Underground waters for farm use, by M. L. Fuller. 1910. 58 pp., 17 pls. 15c.

Discusses rocks as sources of water supply and the relative safety of supplies from different materials; springs and their protection; open or dug and deep wells, their location, yield, relative cost, protection, and safety; advantages and disadvantages of cisterns and combination wells and cisterns.

*257. Well-drilling methods, by Isaiah Bowman. 1911. 139 pp., 4 pls. 15c.

Discusses amount, distribution, and disposal of rainfall, water-bearing rocks, amount of underground water, artesian conditions, and oil and gas bearing formations; gives history of well drilling in Asia, Europe, and the United States; describes in detail the various methods and the machinery used; discusses loss of tools and geologic difficulties; contamination of well waters and methods of prevention; tests of capacity and measurement of depth; and of costs sinking wells.

*258. Underground-water papers, 1910, by M. L. Fuller, F. G. Clapp, G. C. Matson, Samuel Sanford, and H. C. Wolff. 1911. 123 pp., 2 pls. 15c.

Contains the following papers (scope indicated by titles) of general interest:
Drainage of wells, by M. L. Fuller.
Freezing of wells and related phenomena, by M. L. Fuller.
Pollution of underground waters in limestone, by G. C. Matson.
Protection of shallow wells in sandy deposits, by M. L. Fuller.
Magnetic wells, by M. L. Fuller.

259. The underground waters of southwestern Ohio, by M. L. Fuller and F. G. Clapp, with a discussion of the chemical character of the waters, by R. B. Dole. 1912. 228 pp., 9 pls. 35c.

Describes the topography, climate, and geology of the region, the water-bearing formations, the source, mode of occurrence, and head of the waters, and municipal supplies; gives details by counties; discusses in supplement, under chemical character, method of analysis and expression of results, mineral constituents, effect of the constituents on waters for domestic, industrial, and medicinal uses, methods of purification, chemical composition; many analyses and field assays. The matter in the supplement was also published in Water-Supply Paper 254 (The underground waters of north-central Indiana).

274. Some stream waters of the western United States, with chapters on sediment carried by the Rio Grande and the industrial application of water analyses, by Herman Stabler. 1911. 188 pp. 15c.

Describes collection of samples, plan of analytical work, and methods of analyses; discusses soap-consuming power of waters, water softening, boiler waters, and water for irrigation; gives results of analyses of waters of the Rio Grande and of Pecos, Gallinas, and Hondo rivers.

*315. The purification of public water supplies, by G. A. Johnson. 1913. 84 pp., 8 pls. 10c.

Discusses ground, lake, and river waters as public supplies, development of waterworks systems in the United States, water consumption, and typhoid fever; describes methods of filtration and sterilization of water and municipal water softening.

334. The Ohio Valley flood of March–April, 1913 (including comparisons with some earlier floods), by A. H. Horton and H. J. Jackson. 1913. 96 pp., 22 pls. 20c.

Although relating specifically to floods in the Ohio Valley, this report discusses also the causes of floods and the prevention of damage by floods.

337. The effects of ice on stream flow, by William Glenn Hoyt. 1913. 77 pp., 7 pls. 15c.

Discusses methods of measuring the winter flow of streams.

*345. Contributions to the hydrology of the United States, 1914. N. C. Grover, chief hydraulic engineer. 1915. 225 pp., 17 pls. 30c.

*(*e*) A method of determining the daily discharge of rivers of variable slope, by M. R. Hall, W. E. Hall, and C. H. Pierce, pp. 53–65.
Scope indicated by title.

364. Water analyses from the laboratory of the United States Geological Survey, tabulated by F. W. Clarke, chief chemist. 1914. 40 pp. 5c.

Contains analyses of waters from rivers, lakes, wells, and springs in various parts of the United States, including analyses of the geyser water of Yellowstone National Park, hot springs in Montana, brines from Death Valley, water from the Gulf of Mexico, and mine waters from Tennessee, Michigan, Missouri and Oklahoma, Montana, Colorado and Utah, Nevada and Arizona, and California.

371. Equipment for current-meter gaging stations, by G. J. Lyon. 1915. 64 pp., 37 pls. 20c.

Describes methods of installing automatic and other gages and of constructing gage wells, shelters, and structures for making discharge measurements and artificial controls.

*375. Contributions to the hydrology of the United States, 1915. N. C. Grover, chief hydraulic engineer. 1916. 181 pp., 9 pls. 15c.

(*c*) The relation of stream gaging to the science of hydraulics, by C. H. Pierce and R. W. Davenport, pp. 77–84.
(*e*) A method of correcting river discharge for a changing stage, by B. E Jones, pp. 117–130.
(*f*) Conditions requiring the use of automatic gages in obtaining records of stream flow, by C. H. Pierce, pp. 131–139.
Three papers presented at the conference of engineers of the water-resources branch in December, 1914.

*400. Contributions to the hydrology of the United States, 1916. N. C. Grover, chief hydraulic engineer.

(*a*) The people's interest in water-power resources, by G. O. Smith, pp. 1–8.
(*c*) The measurement of silt-laden streams, by Raymond C. Pierce, pp. 39–51.
(*d*) Accuracy of stream-flow data, by N. C. Grover and J. C. Hoyt, pp. 53–59.

416. The divining rod, a history of water witching, with a bibliography, by Arthur J Ellis. 1917. 59 pp. 10c.

A brief paper published "merely to furnish a reply to the numerous inquiries that are continually being received from all parts of the country" as to the efficacy of the divining rod for locating underground water.

425. Contributions to the hydrology of the United States, 1917; N. C. Grover, chief hydraulic engineer. 1918. Contains:

(*c*) Hydraulic conversion tables and convenient equivalents, pp. 71–94. 1917.

427. Bibliography and index of the publications of the United States Geological Survey relating to ground water, by O. E. Meinzer. 1918. 169 pp., 1 pl.

Includes publications prepared, in whole or part, by the Geological Survey that treat any phase of the subject of ground water or any subject directly applicable to ground water. Illustrated by map showing reports that cover specific areas more or less thoroughly.

ANNUAL REPORTS.

*Fifth Annual Report of the United States Geological Survey, 1883–84, J. W. Powell, Director. 1885. xxxvi, 469 pp., 58 pls. $2.25. Contains:

*The requisite and qualifying conditions of artesian wells, by T. C. Chamberlin, pp. 125–173, Pl. 21. Scope indicated by title.

Twelfth Annual Report of the United States Geological Survey, 1890–91, J. W. Powell, Director. 1891. 2 parts. Pt. II, Irrigation, xviii, 576 pp., 93 pls. $2. Contains:

*Irrigation in India, by H. M. Wilson, pp. 375–561, pls. 107–146. See Water-Supply Paper 87.

Thirteenth Annual Report of the United States Geological Survey, 1891–92, J. W. Powell, Director. 1892. (Pts. II and III, 1893.) 3 parts. *Pt. III, Irrigation, xi, 486 pp., 77 pls. $1.85. Contains:

*American irrigation engineering, by H. M. Wilson, pp. 101–349, pls. 111–145. Discusses the economic aspects of irrigation, alkaline drainage, silt, and sedimentation; gives brief history of legislation; describes perennial canals in Idaho-Calofornia, Wyoming, and Arizona; discusses water storage at reservoirs of the California and other projects, subsurface sources of supply, pumping, and subirrigation.

Fourteenth Annual Report of the United States Geological Survey, 1892–93, J. W. Powell, Director. 1893. (Pt. II, 1894.) 2 parts. *Pt. II, Accompanying papers, xx, 597 pp., 73 pls. $2.10. Contains:

*The potable waters of eastern United States, by W. J. McGee, pp. 1–47. Discusses cistern water, stream waters, and ground waters, including mineral springs and artesian wells.

*Natural mineral waters of the United States, by A. C. Peale, pp. 49–88, pls. 3 and 4. Discusses the origin and flow of mineral springs, the source of mineralization, thermal springs, the chemical composition and analysis of spring waters, geographic distribution, and the utilization of mineral waters; gives a list of American mineral spring resorts; contains also some analyses.

Nineteenth Annual Report of the United States Geological Survey, 1897–98, Charles D. Walcott, Director. 1898. (Parts II, III, and V, 1899.) 6 parts in 7 vols. and separate case for maps with Pt. V. *Pt. II, papers chiefly of a theoretic nature, v, 958 pp., 127 pls. $2.65. Contains:

*Principles and conditions of the movements of ground water, by F. H. King, pp. 59–294, pls. 6–16. Discusses the amount of water stored in sandstone, in soil, and in other rocks, the depth to which ground water penetrates; gravitational, thermal, and capillary movements of ground waters, and the configuration of the ground-water surface; gives the results of experimental investigations on the flow of air and water through a rigid, porous media, and through sand, sandstones, and silts; discusses results obtained by other investigators, and summarizes results of observations; discusses also rate of flow of water through sand and rock, the growth of rivers, rate of filtration through soil, interference of wells, etc.

*Theoretical investigation of the motion of ground waters, by C. S. Slichter, pp. 295–384, pls. 17. Scope indicated by title.

PROFESSIONAL PAPERS.

*72. Denudation and erosion in the southern Appalachian region and the Monongahela basin, by L. C. Glenn. 1911. 137 pp., 21 pls. 35c.

Describes the topography, geology, drainage, forests, climate and population, and transportation facilities of the region, the relation of agriculture, lumbering, mining, and power development to erosion and denudation, and the nature, effects, and remedies of erosion; gives details of conditions in Holston, Nolichucky, French Broad, Little Tennessee, and Hiwassee river basins, along Tennessee River proper, and in the basins of the Coosa-Alabama system, Chattahoochee, Savannah, Saluda, Broad, Catawba, Yadkin, New, and Monongahela rivers.

86 The transportation of débris by running water, by G. K. Gilbert, based on experiments made with the assistance of E. C. Murphy. 1914. 263 pp., 3 pls. 70c.

The results of an investigation which was carried on in a specially equipped laboratory at Berkeley, Cal., and was undertaken for the purpose of learning "the laws which control the movement of bed load and especially to determine how the quantity of load is related to the stream slope and discharge and to the degree of comminution of the débris."

A highly technical report.

105. Hydraulic mining débris in the Sierra Nevada, by G. K. Gilbert. 154 pp., 34 pls. 1917.

Presents the results of an investigation undertaken by the United States Geological Survey in response to a memorial from the California Miners' Association asking that a particular study be made of portions of the Sacramento and San Joaquin valleys affected by detritus from torrential streams. The report deals largely with geologic and physiographic aspects of the subject, traces the physical effects, past and future, of the hydraulic mining of earlier decades, the similar effects which certain other industries induce through stimulation of the erosion of the soil, and the influence of the restriction of the area of inundation by the construction of levees. Suggests cooperation by several interests for the control of the streams now carrying heavy loads of débris.

BULLETINS.

*32. Lists and analyses of the mineral springs of the United States (a preliminary study), by A. C. Peale. 1886. 235 pp.

Defines mineral waters, lists the springs by States, and gives tables of analyses so far as available.

*264. Record of deep-well drilling for 1904, by M. L. Fuller, E. F. Lines, and A. C. Veatch. 1905. 106 pp. 10c.

*298. Record of deep-well drilling for 1905, by M. L. Fuller and Samuel Sanford. 1906. 299 pp. 25c.

Bulletins 264 and 298 discuss the importance of accurate well records to the driller, to owners of oil, gas, and water wells, and to the geologist; describe the general methods of work; give tabulated records of wells by States, and detailed records selected as affording valuable stratigraphic information.

*319. Summary of the controlling factors of artesian flows, by Myron L. Fuller, 1908. 44 pp. 10c.

Describes underground reservoirs, the sources of underground waters, the confining agents, the primary and modifying factors of artesian circulation, the essential and modifying factors of artesian flow, and typical artesian systems.

*479. The geochemical interpretation of water analyses, by Chase Palmer. 1911. 31 pp. 5c.

Discusses the expression of chemical analyses, the chemical character of water and the properties of natural waters; gives a classification of waters based on property values and reacting values, and discusses the character of the waters of certain rivers as interpreted directly from the results of analyses; discusses also the relation of water properties to geologic formations, silica in river water, and the character of the water of the Mississippi and the Great Lakes and St. Lawrence River as indicated by chemical analyses.

616. The data of geochemistry (third edition), by F. W. Clarke. 1916. 821 pp. 45c.

Earlier editions were published as Bulletins 330 and 491. Contains a discussion of the statement and interpretation of water analyses and a chapter on "Mineral wells and springs" (pp. 179-216). Discusses the definition and classification of mineral waters, changes in the composition of water, deposits of calcareous, ocherous, and siliceous materials made by water, vadose and juvenile waters, and thermal springs in relation to volcanism. Describes the different kinds of ground water and gives typical analyses. Includes a brief bibliography of papers containing water analyses.

INDEX BY AREAS AND SUBJECTS.

[A—Annual Report; M—Monograph; B—Bulletin; P—Professional Paper; W—Water-Supply Paper; G F—Geologic folio.]

[1] Many of the reports contain brief subject bibliographies. See abstracts.
[2] Many analyses of river, spring, and well waters are scattered through publications, as noted in abstracts.

SURFACE WATER SUPPLY OF HUDSON BAY AND UPPER MISSISSIPPI RIVER BASINS, 1917.

AUTHORIZATION AND SCOPE OF WORK.

This volume is one of a series of 14 reports presenting records of measurements of flow made on streams in the United States during the year ending September 30, 1917.

The data presented in these reports were collected by the United States Geological Survey under the following authority contained in the organic law (20 Stat. L., p. 394):

Provided, That this officer [the Director] shall have the direction of the Geological Survey and the classification of public lands and examination of the geological structure, mineral resources, and products of the national domain.

The work was begun in 1888 in connection with special studies relating to irrigation in the arid West. Since the fiscal year ending June 30, 1895, successive sundry civil bills passed by Congress have carried the following item and appropriations:

For gaging the streams and determining the water supply of the United States, and for the investigation of underground currents and artesian wells, and for the preparation of reports upon the best methods of utilizing the water resources.

Annual appropriations for the fiscal years ending June 30, 1895–1918.

1895	$12,500
1896	20,000
1897 to 1900, inclusive	50,000
1901 to 1902, inclusive	100,000
1903 to 1906, inclusive	200,000
1907	150,000
1908 to 1910, inclusive	100,000
1911 to 1918, inclusive	150,000

In the execution of the work many private and State organizations have cooperated either by furnishing data or by assisting in collecting data. Acknowledgments for cooperation of the first kind are made in connection with the description of each station affected; cooperation of the second kind is acknowledged on page 11.

Measurements of stream flow have been made at about 4,250 points in the United States and also at many points in Alaska and the Hawaiian Islands. In July, 1917, 1,180 gaging stations were being maintained by the Survey and the cooperating organizations. Many miscellaneous discharge measurements are made at other points. In connection with this work data were also collected in regard to precipitation, evaporation, storage reservoirs, river profiles, and water power in many sections of the country and will be made available in water-supply papers from time to time. Information in regard to publications relating to water resources is presented in the appendix to this report.

DEFINITION OF TERMS.

The volume of water flowing in a stream—the "run-off" or "discharge"—is expressed in various terms, each of which has become associated with a certain class of work. These terms may be divided into two groups—(1) those that represent a rate of flow, as second-feet, gallons per minute, miner's inches, and discharge in second-feet per square mile, and (2) those that represent the actual quantity of water, as run-off in depth in inches, acre-feet, and millions of cubic feet. The principal terms used in this series of reports are second-feet, second-feet per square mile, run-off in inches, acre-feet, and millions of cubic feet. They may be defined as follows:

"Second-feet" is an abbreviation for "cubic feet per second." A second-foot is the rate of discharge of water flowing in a channel of rectangular cross section 1 foot wide and 1 foot deep at an average velocity of 1 foot per second. It is generally used as a fundamental unit from which others are computed.

"Second-feet per square mile" is the average number of cubic feet of water flowing per second from each square mile of area drained, on the assumption that the run-off is distributed uniformly both as regards time and area.

"Run-off (depth in inches)" is the depth to which an area would be covered if all the water flowing from it in a given period were uniformly distributed on the surface. It is used for comparing run-off with rainfall, which is usually expressed in depth in inches.

An "acre-foot," equivalent to 43,560 cubic feet, is the quantity required to cover an acre to the depth of 1 foot. The term is commonly used in connection with storage for irrigation.

"Millions of cubic feet" is applied to quantities of water stored in reservoirs, most frequently in connection with studies of flood control.

The following terms not in common use are here defined:

"Stage-discharge relation," an abbreviation for the term "relation of gage height to discharge."

"Control," a term used to designate the section or sections of the stream channel below the gage which determine the stage-discharge relation at the gage. It should be noted that the control may not be the same section or sections at all stages.

The "point of zero flow" for a gaging station is that point on the gage—the gage height—to which the surface of the river falls when the discharge is reduced to zero.

WATER-STAGE RECORDERS.

EXPLANATION OF DATA.

The data presented in this report cover the year beginning October 1, 1916, and ending September 30, 1917. At the beginning of January in most parts of the United States much of the precipitation in the preceding three months is stored as ground water in the form of snow or ice, or in ponds, lakes, and swamps, and this stored water passes off in the streams during the spring break-up. At the end of September, on the other hand, the only stored water available for run-off is possibly a small quantity in the ground; therefore the run-off for the year beginning October 1 is practically all derived from precipitation within that year.

The base data collected at gaging stations consist of records of stage, measurements of discharge, and general information used to supplement the gage heights and discharge measurements in determining the daily flow. The records of stage are obtained either from direct readings on a staff gage or from a water-stage recorder that gives a continuous record of the fluctuations. Measurements of discharge are made with a current meter. (See Pls. I, II.) The general methods are outlined in standard textbooks on the measurement of river discharge.

From the discharge measurements rating tables are prepared that give the discharge for any stage, and these rating tables, when applied to the gage heights, give the discharge from which the daily, monthly, and yearly means of discharge are determined.

The data presented for each gaging station in the area covered by this report comprise a description of the station, a table giving records of discharge measurements, a table showing the daily discharge of the stream, and a table of monthly and yearly discharge and run-off.

If the base data are insufficient to determine the daily discharge, tables giving daily gage height and records of discharge measurements are published.

The description of the station gives, in addition to statements regarding location and equipment, information in regard to any conditions that may affect the permanence of the stage-discharge relation, covering such subjects as the occurrence of ice, the use of the stream for log driving, shifting of control, and the cause and effect of backwater; it gives also information as to diversions that decrease the flow at the gage, artificial regulation, maximum and minimum recorded stages, and the accuracy of the records.

The table of daily discharge gives, in general, the discharge in second-feet corresponding to the mean of the gage heights read each day. At stations on streams subject to sudden or rapid diurnal fluctuation the discharge obtained from the rating table and the mean daily gage height may not be the true mean discharge for the day. If such stations are equipped with water-stage recorders the mean daily discharge may be obtained by averaging discharge at regular intervals during the day, or by using the discharge integrator, an instrument operating on the principle of the planimeter and containing as an essential element the rating curve of the station.

In the table of monthly discharge the column headed "Maximum" gives the mean flow for the day when the mean gage height was highest. As the gage height is the mean for the day it does not indicate correctly the stage when the water surface was at crest height, and the corresponding discharge was consequently larger than given in the maximum column. Likewise, in the column headed "Minimum" the quantity given is the mean flow for the day when the mean gage height was lowest. The column headed "Mean" is the average flow in cubic feet per second during the month. On this average flow computations recorded in the remaining columns, which are defined on page 8, are based.

The deficiency table presented for some of the gaging stations shows the number of days in each year on which the mean daily discharge was less than the discharge given in the table. By subtraction the table gives the number of days each year that the mean daily discharge was between the discharges given in the table and, also by subtraction, the number of days that the mean daily discharge was equal to or greater than the discharge given. If one discharge rating table was used throughout the period covered by the deficiency table, gage heights that correspond to the discharges are also given.

ACCURACY OF FIELD DATA AND COMPUTED RESULTS.

The accuracy of stream-flow data depends primarily (1) on the permanence of the stage-discharge relation and (2) on the accuracy of observation of stage, measurements of flow, and interpretation of records.

A paragraph in the description of the station gives information regarding the (1) permanence of the stage-discharge relation, (2) precision with which the discharge rating curve is defined, (3) refinement of gage readings, (4) frequency of gage readings, and (5) methods of applying daily gage heights to the rating table to obtain the daily discharge.[1]

For the rating tables "well defined" indicates, in general, that the rating is probably accurate within 5 per cent; "fairly well defined," within 10 per cent; "poorly defined," within 15 to 25 per cent. These notes are very general and are based on the plotting of the individual measurements with reference to the mean rating curve.

[1] For a more detailed discussion of the accuracy of stream-flow data see Grover, N. C., and Hoyt, J. C., Accuracy of stream-flow data: U. S. Geol. Survey Water-Supply Paper 400, pp. 53-59, 1916.

The monthly means for any station may represent with high accuracy the quantity of water flowing past the gage, but the figures showing discharge per square mile and depth of run-off in inches may be subject to gross errors caused by the inclusion of large non-contributing districts in the measured drainage area, by lack of information concerning water diverted for irrigation or other use, or by inability to interpret the effect of artificial regulation of the flow of the river above the station. "Second-feet per square mile" and "Run-off (depth in inches)" are therefore not computed if such errors appear probable. The computations are also omitted for stations on streams draining areas in which the annual rainfall is less than 20 inches. All figures representing "second-feet per square mile" and "run-off (depth in inches)" previously published by the Survey should be used with caution because of possible inherent sources of error not known to the Survey.

The table of monthly discharge gives only a general idea of the flow at the station and should not be used for other than preliminary estimates; the tables of daily discharge allow more detailed studies of the variation in flow. It should be borne in mind, however, that the observations in each succeeding year may be expected to throw new light on data previously published.

COOPERATION.

In Montana the work was done in cooperation with the United States Reclamation Service. The station on St. Mary River at Kimball, Alberta, was maintained in cooperation with the Canadian Department of Interior.

In Minnesota the work was carried on in cooperation with the State Drainage Commission, E. V. Willard, acting State drainage engineer, under terms of an act of the legislature of 1909 as embodied in joint resolution 19, which reads as follows:

> Whereas the water supplies, water powers, navigation of our rivers, drainage of our lands, and the sanitary condition of our streams and their watersheds generally form one great asset and present one great problem, therefore:
>
> *Be it resolved by the house of representatives, the senate concurring,* That the State drainage commission be, and is hereby, directed to investigate progress in other States toward the solution of said problem in such States, to investigate and determine the nature of said problems in this State.

The International Joint Commission maintained the water-stage recorder and paid the salary of the observer at the station on Kawishiwi River near Winton, and the United States Engineer Corps paid the salaries of the observers at the stations on Minnesota River near Montevideo and Chippewa River near Watson.

In Wisconsin the work was carried on in cooperation with the Railroad Commission of Wisconsin, C. M. Larson, chief engineer, and at certain stations with the following organizations: Wisconsin-

Minnesota Light & Power Co. (Chippewa River at Chippewa Falls, Red Cedar River near Colfax, Red Cedar River at Cedar Falls, Red Cedar River at Menomonie), Chippewa & Flambeau Improvement Co. (Chippewa River at Bishops Bridge near Winter), Stoughton Municipal Electric Light System (Yahara River near Edgerton).

In Iowa the work was carried on in cooperation with the Iowa Geological Survey, George F. Kay, director, and the Mississippi River Power Co., of Keokuk, Iowa.

In Illinois work was carried on in cooperation with the State of Illinois, through the Rivers and Lakes Commission until June 30, and the Division of Waterways of Public Works and Buildings afterward, and at single stations with the United States Army Engineer Corps (Illinois River at Peoria) and the Central Illinois Public Service Co. (South Fork of Sangamon River at power plant near Taylorville).

DIVISION OF WORK.

The data for stations in the Hudson Bay basin, except in Minnesota, were collected and prepared for publication under the direction of W. A. Lamb, district engineer, Helena, Mont., assisted by A. H. Tuttle and E. F. Chandler.

The data for stations in the Hudson Bay and Mississippi River basins in Minnesota were collected and prepared for publication under the direction of W. G. Hoyt, district engineer, assisted by S. B. Soulé and R. B. Kilgore, and by E. F. Chandler, assisted by T. M. Wardwell, L. B. Dale, and H. A. Noble.

For stations in the Mississippi River basin in Wisconsin the data were collected for publication under the direction of W. G. Hoyt, assisted by E. L. Williams, R. B. Kilgore, F. W. Huels, and J. P. Schwada.

For stations in the Mississippi River basin in Iowa the data were collected under the general direction of W. G. Hoyt and under the immediate direction of R. H. Bolster, assisted by C. Herlofson and A. Davis. The data for stations in the Mississippi River basin in Illinois were collected under the general direction of W. G. Hoyt and under the immediate direction of H. C. Beckman, assisted by G. J. Trinkaus. A. M. Wohl, H. S. Wohl, and Marcia Towle.

GAGING-STATION RECORDS.

HUDSON BAY DRAINAGE BASINS.

ST. MARY RIVER NEAR BABB, MONT.

[Including diversion from Swiftcurrent Creek.]

LOCATION.—About 1,040 feet above the headworks of St. Mary canal, one-fourth mile below outlet of Lower St. Mary Lake, and 2 miles south of Babb, on Blackfeet Indian Reservation, in Teton County.

DRAINAGE AREA.—278 square miles (including area of Swiftcurrent Creek above point of diversion into St. Mary Lake).

RECORDS AVAILABLE.—April 9, 1902, to September 30, 1917. Records prior to October, 1915, do not include the flow of Swiftcurrent Creek.

GAGE.—Chain gage on right bank. During the winter months a temporary low-water gage opposite the chain gage was read. Gages read by employees of the United States Reclamation Service.

DISCHARGE MEASUREMENTS.—Made from cable 560 feet below gage, or by wading. Until September, 1909, the cable was at a point about 300 feet downstream from its present location.

CHANNEL AND CONTROL.—Bed of stream practically permanent. Banks high and not subject to overflow. The concrete diversion dam for the St. Mary canal, located 1,040 feet below the gage, forms the control. The dam is provided with flashboard sluice gates near the canal headgates. Stage-discharge relation is permanent when the flashboards in the sluice gates remain at the level of the crest of the dam.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 5.60 feet June 10 and 11 (discharge, 4,160 second-feet); minimum discharge, 66 second-feet April 1.

1902–1917: Maximum stage estimated at 9.4 feet June 5, 1908 (discharge, 7,980 second-feet); minimum discharge, 20 second-feet, April 3–7, 1904.

ICE.—Stage-discharge relation affected by ice for short periods.

DIVERSIONS.—None.

REGULATION.—Natural storage in St. Mary Lakes. The flow of Swiftcurrent Creek was diverted into lower St. Mary Lake on October 1, 1915. The flow of this stream will be regulated by Sherburne Lake reservoir.

ACCURACY.—Stage-discharge relation permanent when flashboards in sluice gates of dam are kept at level of crest of dam. Four rating curves have been developed and used for the periods noted: October 1–10, fairly well defined; October 11 to December 4 and April 11–19, and July 23 to September 9, well defined; April 20 to July 22 and September 13–30, well defined; January 6 to April 5, poorly defined. Gage read twice daily during the open season and once daily in winter. Daily discharge ascertained by applying daily gage height to rating table except for periods affected by ice or by shifting control. Discharge, December 5 to January 5 estimated from temperature records and notes by observer. Records good.

The diversion dam below the gaging station was constructed by the United States Reclamation Service for the purpose of diverting water from St. Mary River into the St. Mary canal, which carries the water across the divide into the North Fork of Milk River. The water then flows in the natural channel of Milk River through Canada, and is finally used for irrigation in the Milk River Valley in Montana. The present capacity of the diversion canal is about 425 second-feet. A storage reservoir is being provided on Swiftcurrent Creek by constructing a dam at the outlet of Sherburne Lake. By means of a diversion channel connecting Swiftcurrent Creek and Lower St. Mary Lake, the run-off from Swiftcurrent Creek is made available for diversion through St. Mary canal.

Discharge measurements of St. Mary River near Babb, Mont., during the year ending Sept. 30, 1917.

[Made by W. A. Lamb.]

[a] Includes drainage area of Swiftcurrent Creek above point of diversion into St. Mary Lake.

ST. MARY RIVER NEAR KIMBALL, ALBERTA.

LOCATION.—In SW. ¼ sec. 25, T. 1 N., R. 25 W. fourth meridian, about 1 mile south of Kimball, Alberta, and 5 miles north of international boundary.

DRAINAGE AREA.—472 square miles (measured on topographic maps).

RECORDS AVAILABLE.—January 1, 1913, to September 30, 1917. From September 4, 1902, to December 31, 1912, records were obtained at a point one-fourth mile below the boundary line. Records were also obtained by the Irrigation Branch (now the Reclamation Service), Department of the Interior, Canada, at a point about half a mile below the present station, from 1905 to 1912. The discharge at the three points is practically the same.

GAGE.—Stevens water-stage recorder with a concrete well and shelter on the right bank used during the open-water season. A staff gage at cable from which discharge measurements were made was used October 1 to November 8. A chain gage attached to the highway bridge 2 miles below the station was used November 10 to May 5 when stage-discharge relation was affected by ice.

DISCHARGE MEASUREMENTS.—Made from a cable three-fourths of a mile below the gage; low-water measurements made by wading near the cable.

CHANNEL AND CONTROL.—Bed of stream at the gage and at the control is composed of boulders and sandstone ledges. The control is formed by an outcropping ledge of sandstone. Stage-discharge relation is affected by a large gravel bar which has formed on the right bank at the control.

EXTREMES OF DISCHARGE.—Maximum stage during year from water-stage recorder, 6.93 feet at 6 p. m. June 11 (discharge, 5,230 second-feet); minimum discharge, 100 second-feet January 30 and 31.

1902–1917: Maximum stage recorded, 12.75 feet, June 5, 1908 (discharge, 18,000 second-feet, estimated by comparison with record for station near Babb); minimum discharge, 70 second-feet,[1] February 5, 1914.

ICE.—Stage discharge relation seriously affected by ice. Daily discharge computed from discharge measurements and temperature records.

DIVERSIONS.—The St. Mary canal, constructed by the United States Reclamation Service, diverts water from St. Mary River near Babb, Mont., to the North Fork of Milk River. During 1917, 33,600 acre-feet was diverted. The Alberta Railway & Irrigation Co. canal diverts from St. Mary River about a mile below the station.

REGULATION.—The flow of Swiftcurrent Creek will be regulated by the Sherburne Lake reservoir, under construction by the United States Reclamation Service.

ACCURACY.—Stage-discharge relation changed during high water June 9–13; affected by ice November 10 to May 5. Rating curves used as follows: October 1 to November 8, fairly well defined; May 7 to June 8, well defined between 470 and 4,000 second-feet; June 14 to September 30 well defined between 200 and 5,000 second-feet. Staff gage read to hundredths twice daily October 1 to November 9; chain gage read November 10 to May 5. Gage heights May 7 to September 30 obtained from recorder graph by averaging the stage for hourly intervals. Daily discharge ascertained by applying mean daily gage height to rating table except for periods during which stage-discharge relation was affected by shifting control or ice. Records good.

COOPERATION.—Station maintained jointly with the Reclamation Service, Department of the Interior of Canada.

---

[1] Only estimates of mean monthly flow are available for the winter periods from 1902 to 1912, inclusive, and a lower minimum discharge may have occurred during that time.

Discharge measurements of St. Mary River near Kimball, Alberta, during the year ending Sept. 30, 1917.

The year	5,200	100	988	715,000

NOTE.—For table of monthly discharge of St. Mary canal at Douglas bridge, see p. 22.

SWIFTCURRENT CREEK AT MANY GLACIER, MONT.

LOCATION.—In sec. 12, T. 35 N., R. 16 W., at outlet of McDermott Lake at Many Glacier, in Glacier National Park, about 14 miles southwest of Babb, in Teton County.

DRAINAGE AREA.—31.4 square miles (measured on topographic map).

RECORDS AVAILABLE.—June 6, 1912, to September 30, 1917.

GAGE.—Vertical staff on the right bank at the outlet of the lake. Prior to May 23, 1916, a staff gage on the left bank opposite the present gage was read. Gage read by George Hall.

DISCHARGE MEASUREMENTS.—Made by wading at the outlet of the lake or below the falls. High-water measurements made from the highway bridge above the power house; measuring section at the bridge very poor.

CHANNEL AND CONTROL.—Control is a limestone outcrop at the outlet of the lake.

EXTREMES OF DISCHARGE.—Maximum stage recorded during the year, 4.20 feet at 6 p. m. June 9 (discharge, 1,220 second-feet); minimum discharge, 20 second-feet, by current-meter measurement, April 14, when stage-discharge relation was seriously affected by ice. No record of discharge January 1 to April 13.

1912–1917: Maximum stage recorded, 4.75 feet, June 17, 1916 (discharge, 1,550 second-feet); minimum discharge, 10.8 second-feet, March 19, 1912, measured by current meter.

ICE.—Stage-discharge relation seriously affected by ice January 1 to April 17. Ice cover on lake November 20 to June 9; records for December may be slightly in error on account of ice.

DIVERSIONS.—None.

REGULATION.—None.

ACCURACY.—Stage-discharge relation probably permanent during year; seriously affected by ice. Rating curve used October 1 to December 31, and April 18 to September 30, well defined between 44 and 825 second-feet, but no current-meter measurements were made during open season. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Discharge, April 14, obtained from current-meter measurement of that date; April 15–17 interpolated because of ice. Records probably fair, but owing to lack of discharge measurements should be used with caution.

The following discharge measurement was made by W. A. Lamb: April 14, 1917: Gage height, 1.48 feet; discharge, 19.6 second-feet (stage-discharge relation affected by ice).

Daily discharge, in second-feet, of Swiftcurrent Creek at Many Glacier, Mont., for the year ending Sept. 30, 1917.

SWIFTCURRENT CREEK AT SHERBURNE, MONT.

LOCATION.—In sec. 35, T. 36 N., R. 15 W., near outlet of Lower Sherburne Lake, in Teton County.

DRAINAGE AREA.—64 square miles (measured on topographic map).

RECORDS AVAILABLE.—July 1, 1912, to September 30, 1917.

GAGE.—Staff gage on left bank about 300 feet below the spillway of the Sherburne Lake dam; read by employees of the United States Reclamation Service. From July 1, 1912, to November 9, 1914, a vertical staff gage was maintained on the left bank near the outlet of the lake, and at a different datum from the present gage.

DISCHARGE MEASUREMENTS.—Made by wading or from cable 50 feet below gage.

CHANNEL AND CONTROL.—An outcropping limestone ledge, somewhat broken and irregular, forms the control; subject to slight shifts.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year 5.55 feet June 9–11 (discharge 1,070 second-feet); minimum stage 0.40 foot at 8 a. m. May 4 (discharge 6 second-feet).

1912–1917: Maximum stage recorded 7.85 feet June 17, 1916 (discharge 2,280 second-feet); minimum stage 0.5 foot April 25, 1916 (discharge 4 second-feet).

ICE.—Stage-discharge relation not seriously affected by ice.

DIVERSION.—None.

REGULATION.—The natural flow of the stream was affected by placing and removing flashboards on the temporary construction dam built at the outlet in connection with the Sherburne Lake storage dam.

ACCURACY.—Stage-discharge relation changed probably March 27. Rating curves used October 1 to March 27 and March 28 to September 30 are well defined. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records good.

Discharge measurements of Swiftcurrent Creek at Sherburne, Mont., during the year ending Sept. 30, 1917.

U. S. RECLAMATION SERVICE ST. MARY CANAL AT HUDSON BAY DIVIDE, NEAR BROWNING, MONT.

Location.—At Douglas bridge on the Hudson Bay divide, 3 miles above the outlet of the canal, 30 miles directly north of Browning on the Blackfeet Indian Reservation.

Records available.—July 3 to September 13, 1917.

Gage.—A vertical staff, graduated to tenths, nailed to upstream side of left pier of bridge; read by U. S. Reclamation Service ditch rider.

Discharge measurements.—Made from upstream side of bridge at the gage.

Channel and control.—The channel is uniform, but the slope varies with the stage. Control is a V-shaped concrete drop 1 mile below the gage.

EXTREMES OF DISCHARGE.—Maximum discharge during the year 254 second-feet.

REGULATION.—The flow is regulated at the headgates 26 miles above. A small reservoir at Spider Lake serves to equalize sudden changes at the headgates.

ACCURACY.—Stage-discharge relation practically permanent. Gage read to tenths once daily. Discharge computed by using a rating curve based on discharge measurements made in 1918 and measurements of North Fork of Milk River at Peter's Ranch below the outlet of the canal. Records fair.

St. Mary canal diverts from St. Mary River near Babb, Mont., and carries the water across the divide into North Fork of Milk River. The water is used for irrigation in the Milk River valley in Montana.

Daily discharge, in second-feet, of U. S. Reclamation Service St. Mary canal at Hudson Bay divide, near Browning, Mont., for the year ending Sept. 30, 1917.

OTTERTAIL RIVER AT GERMAN CHURCH, NEAR FERGUS FALLS, MINN.

LOCATION.—At highway bridge on south line of sec. 31, T. 134 N., R. 42 W., about 5 miles upstream from old station known as "Ottertail River, near Fergus Falls," and about 8 miles north of Fergus Falls, Ottertail County.

DRAINAGE AREA.—1,300 square miles.

RECORDS AVAILABLE.—October 29, 1913, to September 30, 1917, when station was discontinued. May 9, 1904, to October 22, 1913, records were collected at a station about 5 miles downstream from the present site. The drainage area at the lower station is only 10 square miles larger than at the upper, and no tributaries intervene.

GAGE.—Chain gage attached to the downstream handrail near the right bank; read by D. S. Danielson.

DISCHARGE MEASUREMENTS.—Made from downstream side of the bridge.

CHANNEL AND CONTROL.—Bed composed of sand, gravel, and boulders. Rapids about 100 feet below the gage form a well-defined control, which is practically permanent except for an occasional slight growth of vegetation in the channel. Banks at and above the gage are high; probably not subject to overflow. At the control the land adjacent to the left bank is low and will be overflowed at a stage of about 5 feet.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 2.45 feet October 2, 3, 12, and 13 (discharge, 613 second-feet); minimum stage recorded, 0.88 foot Sept. 10 and 11 (discharge, about 121 second-feet).

1914–1917: Maximum stage recorded, 3.0 feet at 8.30 a. m. June 29, 1916 (discharge, 982 second-feet); minimum stage recorded September 10, 11, 1917.

ICE.—Stage-discharge relation seriously affected by ice.

REGULATION.—Fluctuations caused by the operation of a number of dams and small mills above the station are equalized by small lakes through which the river flows before reaching the station, so that they are not observable at the gage.

ACCURACY.—Stage-discharge relation permanent except as affected by ice. Rating curve well defined between 237 and 837 second-feet; extended and subject to error outside these limits. Gage read to quarter-tenths once daily; fluctuations in stage so gradual that good results are obtained from one reading a day. Daily discharge ascertained by applying daily gage height to rating table except for period when stage-discharge relation was affected by ice, for which it was obtained by applying to rating table daily gage height corrected for effect of ice by means of discharge measurements, observer's notes, and weather records. Open water records excellent, except those for low stages, which are subject to error; winter records good.

Discharge measurements of Ottertail River at German Church, near Fergus Falls, Minn., during the year ending Sept. 30, 1917.

RED RIVER AT FARGO, N. DAK.

Location.—At dam half a mile above highway bridge connecting Front Street, Fargo, N. Dak., with Moorhead, Minn., 10 miles above mouth of Sheyenne River.

Drainage area.—6,020 square miles.

Records available.—May 27, 1901, to September 30, 1917.

Gage.—Vertical staff attached to tree on left bank about 6 rods above the dam; vertical staff for use at low stages attached to upper end of fishway at left end of dam; lowest point of crest of dam now about 0.90 foot above datum of gage. Prior to September 1, 1914, gage readings were obtained from a vertical staff attached to the breakwater for the center pier of the Front Street bridge; this gage is still maintained and used by the Weather Bureau but can not be read accurately without a field glass and its control is less permanent than that of the gage now used. The datum of the Front Street gage is such that if the dam were removed, or if the stage were so high as to completely drown the dam, readings on the Front Street gage would be about 10.4 feet greater than on the gage now used. At extreme low stage the fall over the dam is about 5 feet.

Discharge measurements.—Made from footbridge a few feet upstream from gage.

Channel and control.—Bed consists of clay and silt; nearly permanent. Dam below gage is the control.

Extremes of discharge.—Maximum stage during year, 14.0 feet April 4 (discharge, 5,200 second-feet); minimum stage, 1.25 feet September 15 (discharge, 42 second-feet).

1901–1917: Maximum stage recorded, 19.9 feet April 6, 1916, when stage-discharge relation was affected by ice; maximum discharge, 7,440 second-feet April 7, 1916; minimum stage recorded, 5.7 feet November 1, 1910 (discharge, 36 second-feet).

Ice.—Stage-discharge relation not seriously affected by ice during winter; open-season rating table is applicable by making small correction for slight obstruction of crest of dam; in determining flow during spring break-up, however, corrections amounting to several feet must be applied to gage heights before applying open-season rating table, owing to backwater from ice.

Diversions.—None.

Regulation.—No power plants or storage above the station within 60 miles; storage not great enough to noticeably affect the discharge at the station.

ACCURACY.—Stage-discharge relation practically permanent during year except as affected by ice. Rating curve well defined between 200 and 2,400 second-feet and fairly well defined at other stages. Gage read to hundredths daily. Open-water records good.

Discharge measurements of Red River at Fargo, N. Dak., during the year ending Sept. 30, 1917.

RED RIVER AT GRAND FORKS, N. DAK.

LOCATION.—At Northern Pacific Railway bridge between Grand Forks, N. Dak., and East Grand Forks, Minn., half a mile below mouth of Red Lake River.

DRAINAGE AREA.—25,000 square miles.

RECORDS AVAILABLE.—May 26, 1901, to September 30, 1917. Gage-height records have been kept by the United States Engineer Corps since 1882 and a few discharge measurements were made by them in early years.

GAGE.—Chain gage attached to Northern Pacific Railway bridge and vertical staff gage attached to ice breaker below center pier of same bridge. The staff gages used by the United States Engineer Corps and the United States Weather Bureau are on the bridge breakwater at the same place as the staff gage used by the United States Geological Survey and at datum 5 feet higher.

DISCHARGE MEASUREMENTS.—Made from Great Northern Railway bridge about a fifth of a mile above the gage.

CHANNEL AND CONTROL.—Clay and silt; shifts very slightly.

EXTREMES OF DISCHARGE.—Maximum stage during year, 33.9 feet at 5 p. m. April 8 (discharge, 21,600 second-feet); minimum stage, 3.4 feet September 4 (discharge, 395 second-feet).

1882-1917: Maximum stage recorded, 50.2 feet April 10, 1897 (discharge, 43,000 second-feet); minimum stage, 2.6 feet February 10, 1912 (discharge, 100 second-feet).

ICE.—Stage-discharge relation seriously affected by ice. The ice cover is usually complete and smooth from late in November until about the beginning of April, and the flow is steady, with few fluctuations. Since 1905 sufficient discharge measurements have been made each winter to obtain fairly accurate summaries of winter flow. For a few days or weeks at the time of the spring break-up the water level is raised considerably by ice in the channel, and at times, as indicated by a few discharge measurements, this abnormal rise has been as much as 8 feet, though usually it is less; correction is made for this rise in applying open-season rating table.

DIVERSION AND REGULATION.—No power plants above station with sufficient storage to cause noticeable variations in the flow.

ACCURACY.—Stage-discharge relation practically permanent during the year except as affected by ice. Rating curve fairly well defined between 400 and 9,000 second-feet. Gage read to half-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table except for period in which stage-discharge relation was affected by ice, for which it was obtained by applying to rating table daily gage height corrected for effect of ice by means of discharge measurements, observer's notes, and weather records. Open-water records good; winter records fair.

Discharge measurements of Red River at Grand Forks, N. Dak., during the year ending Sept. 30, 1917.

MUSTINKA RIVER ABOVE WHEATON, MINN.

LOCATION.—On line between secs. 7 and 8, T. 127 N., R. 46 W., 1 mile upstream from Chicago, Milwaukee & St. Paul Railway crossing, 1½ miles northeast of Wheaton, Traverse County, and 8 miles above Lake Traverse, into which the river discharges.

DRAINAGE AREA.—About 900 square miles.

RECORDS AVAILABLE.—March 23 to September 30, 1917, when station was discontinued. June 7 to November 30, 1916, at point about 3½ miles farther downstream.

GAGE.—Chain gage attached to bridge; read by Henry Heggen.

DISCHARGE MEASUREMENTS.—Made from Chicago, Milwaukee & St. Paul Railway bridge 1 mile downstream from gage, or from highway bridge just below railway bridge.

CHANNEL AND CONTROL.—Bed composed of clay and silt. Control not well defined. Slope of river from station to Lake Traverse is so slight that the stage-discharge relation may possibly be affected by changes in the stage of the lake.

EXTREMES OF DISCHARGE.—Maximum stage during period, 14.7 feet at 6 p. m. April 1 (discharge, about 2,340 second-feet); minimum stage, 1.16 feet August 30, September 1, 4, and 5 (discharge, about 1 second-foot).

ACCURACY.—Stage-discharge relation probably permanent. Rating curve fairly well defined below 2,500 second-feet. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records fair.

Discharge measurements of Mustinka River above Wheaton, Minn., during the year ending Sept. 30, 1917.

WILD RICE RIVER AT TWIN VALLEY, MINN.

LOCATION.—In SW. ¼ sec. 22, T. 144 N., R. 44 W., at highway bridge at Twin Valley, Norman County, 2 miles above a small tributary which enters from the right at Heiberg.

DRAINAGE AREA.—805 square miles.

RECORDS AVAILABLE.—June 30, 1909, to September 30, 1917, when station was discontinued.

GAGE.—Vertical staff gage attached to pier of bridge, at left bank; read by Axel Johnson.

DISCHARGE MEASUREMENTS.—Made from the bridge by wading.

CHANNEL AND CONTROL.—One channel at all stages; bed composed of sand and silt. Control not well defined. Right bank high and wooded; left bank will be overflowed to some extent at stage of 12 feet.

EXTREMES OF DISCHARGE.—Maximum stage recorded, 7.2 feet April 3 (discharge, about 622 second-feet); minimum stage recorded, 4.48 feet, August 27 (discharge, 14 second-feet).

1909–1917: Maximum stage recorded, 20.0 feet at 7 a. m. July 22, 1909 (discharge, about 9,290 second feet); minimum open-water discharge 12 second-feet August 31 and September 1, 1913; minimum winter discharge measured by current meter, 10 second-feet February 5, 1913; the absolute minimum was probably less than this amount.

ICE.—Stage-discharge relation seriously affected by ice.

REGULATION.—Discharge affected by storage created by dams at the lower end of Lower Rice Lake, and at the outlet of Twin Lakes.

ACCURACY.—Stage-discharge relation not permanent; change occurred probably during spring when ice left the river. Rating curve used October 1 to April 1 well defined between 37 and 2,290 second-feet; curve used April 2 to September 30 well defined between 20 and 3,400 second-feet. Gage read to half-tenths twice daily, except November 21 to March 23, when it was read once weekly. Daily discharge ascertained by applying mean daily gage height to rating table, except during period when stage-discharge was affected by ice, for which it was obtained by applying to rating table a weekly gage height corrected for effect of ice by means of discharge measurements, observer's notes and weather records. Open-water records good; winter records fair.

Discharge measurements of Wild Rice River at Twin Valley, Minn., during the year ending Sept. 30, 1917.

DEVILS LAKE NEAR DEVILS LAKE, N. DAK.

LOCATION.—At biologic station of University of North Dakota, near Devils Lake, in Ramsey County, 6 miles southwest of city of Devils Lake.

DRAINAGE AREA.—The theoretical drainage area of the lake is about 3,700 square miles. In years of ordinary rainfall water reaches the lake from only a small part of this area, most of which drains into local depressions and small lakelets, where the water remains until it is lost by evaporation. In 1880 the length of Devils Lake was 35 miles and its area about 120 square miles, but its present area is probably less than 60 square miles.

RECORDS AVAILABLE.—June 8, 1901, to September 30, 1917 (fragmentary).

GAGE.—Staff gage on pier at the biologic station. Zero of gage, 1,393.3 feet above sea level. Previous to 1916 staff gages were placed at convenient points on piers, but it has been necessary to renew them occasionally, sometimes every year, owing to damage caused by ice during the spring break-up. These gages have been reset as near to the correct datum as possible, often by the use of a carpenter's level. Occasionally errors of 0.1 foot in the records have been discovered when accurate checks were made, but no larger errors are likely to occur. The gage is read occasionally by employees of the biologic station.

REGULATION.—The lake has no outlet. The stage of the lake shows the relation between evaporation from the lake surface and the inflow from the surrounding country and gives an indication whether the run-off has been affected by the settlement of the drainage area and cultivation of the land surface.

COOPERATION.—Records are furnished by the North Dakota Biological Survey.

Gage height of Devils Lake near Devils Lake, N. Dak., during the year ending Sept. 30, 1917.

a About 6.9 feet.

RED LAKE RIVER AT THIEF RIVER FALLS, MINN.

LOCATION.—In sec. 33, T. 154 N., R. 43 W., one-third mile below dam at Thief River Falls, Pennington County, and 1 mile below mouth of Thief River, which comes in from the right.

DRAINAGE AREA.—3,430 square miles.

RECORDS AVAILABLE.—July 2, 1909, to September 30, 1917.

GAGE.—Inclined staff gage located on right bank; read by Dedrick Knutson.

DISCHARGE MEASUREMENTS.—Made from cable near gage.

CHANNEL AND CONTROL.—Gravel; practically permanent.

EXTREMES OF DISCHARGE.—Maximum open-water stage recorded, 10.6 feet April 10 (discharge, 5,060 second-feet); minimum open-water stage recorded, 3.61 feet August 26 (discharge, 99 second-feet); minimum discharge estimated at 97 second-feet December 11, when river was frozen over.

1909–1917: Maximum open-water stage recorded, 12.2 feet, April 19–21, 1916 (discharge, 7,040 second-feet); minimum discharge recorded, zero, July 17 and August 27, 1911.

ICE.—Stage-discharge relation seriously affected by ice.

REGULATION.—A short distance above the station is a dam owned by the Hansen & Barzen Milling Co. and the city lighting plant. The variation in load on the turbines, due to the operation of the lighting plant (at night) and of the mill (chiefly during the day), caused fluctuations in the river at the gage.

ACCURACY.—Stage-discharge relation fairly permanent. Rating curve well developed between 19 and 5,600 second-feet. Gage read to half-tenths once daily. Daily discharge ascertained by applying daily gage height to rating table except for period when stage-discharge relation was affected by ice, for which it was obtained by applying to rating table daily gage height corrected for effect of ice by means of discharge measurements, observer's notes, and weather records. Open-water records good except on certain days when diurnal fluctuation was such that one reading would not give mean for day; winter records fair.

RED LAKE RIVER AT CROOKSTON, MINN.

LOCATION.—In sec. 31, T. 150 N., R. 46 W., at new Sampson's Addition highway bridge in Crookston, Polk County, a quarter of a mile below dam and power house of Crookston Waterworks Power & Light Co.'s plant. No tributaries enter for several miles.

DRAINAGE AREA.—5,320 square miles.

RECORDS AVAILABLE.—May 19, 1901, to September 30, 1917.

GAGE.—Barret & Lawrence water-stage recorder on right abutment of bridge; installed in September, 1911; replaced chain gage attached to bridge July 1, 1909; both gages at same datum. Prior to July 1, 1909, gage was on old Sampson's Addition bridge, about 300 feet farther upstream; this gage read the same as the present one at ordinary stages. Gage inspected by Roy Lundahl.

DISCHARGE MEASUREMENTS.—Made from steel highway bridge at gage section.

CHANNEL AND CONTROL.—Control not well defined; one channel at all stages; slightly shifting.

EXTREMES OF DISCHARGE.—Maximum mean daily stage during year, from water-stage recorder, 11.9 feet April 11 (discharge, estimated because of ice at control, about 5,320 second-feet); minimum mean daily stage, from water-stage recorder, 2.39 feet August 30 (discharge, 78 second-feet).

1901–1917: Maximum mean daily stage recorded, 21.5 feet April 17, 1916 (discharge, 14,400 second-feet). A minimum discharge of 10 second-feet was recorded by discharge measurement made January 27, 1912. The flow is controlled to such an extent that the minimum recorded discharge has no bearing on the minimum natural flow.

ICE.—Stage-discharge relation seriously affected by ice.

REGULATION.—Considerable diurnal fluctuation at the gage is caused by the operation of the power plant immediately above the station. The plant has little storage, so that the mean monthly flow should represent nearly the natural flow.

ACCURACY.—Stage-discharge relation fairly permanent throughout the year. Rating curve used well developed between 100 and 10,000 second-feet. Operation of water-stage recorder satisfactory throughout year except during extremely cold weather when records are fragmentary; during such periods readings from chain gage were taken. Daily discharge obtained by applying to rating table mean daily gage height obtained by planimeter from the gage-height graph except for winter period for which it was obtained by applying to the rating table the mean daily gage height corrected for effect of ice by means of discharge measurements, observer's notes, and weather records. Open-water records excellent; winter records subject to error.

Discharge measurements of Red Lake River at Crookston, Minn., during the year ending Sept. 30, 1917.

THIEF RIVER NEAR THIEF RIVER FALLS, MINN.

LOCATION.—In sec. 3, T. 154 N., R. 43 W., at Drybrook ford, Pennington County, 5 miles north of Thief River Falls. Nearest tributary, outlet of Mud Lake, which enters in northeastern part of T. 156 N., R. 42 W.

DRAINAGE AREA.—1,010 square miles.

RECORDS AVAILABLE.—July 1, 1909, to September 30, 1917, when station was discontinued.

GAGE.—Chain gage installed August 26, 1915, on cantilever timber fastened to a tree on right bank. Inclined staff gage, installed September 4, 1913, to replace old inclined staff gage, which was set at incorrect gage datum, was used until August 26, 1915. Gage read by T. H. Risteigen.

DISCHARGE MEASUREMENTS.—Made from steel highway bridge 1,000 feet below the gage; at low stages made by wading near the gage.

CHANNEL AND CONTROL.—Heavy gravel and boulders; nearly permanent; one channel at all stages. Banks high and not subject to overflow.

EXTREMES OF DISCHARGE.—Maximum stage recorded during the year, 12.6 feet April 11 (discharge, 2,550 second-feet); minimum stage 3.63 feet August 25 (discharge 0.5 second-foot).

1909–1917: Maximum stage recorded, 14.5 feet, April 23, 1916 (discharge, 4,080 second-feet); no flow in October, November, and December, 1910, January, February, and December, 1911, January and February, 1912, and February, 1916.

REGULATION.—Dam at Thief River Falls at the mouth of Thief River, backs up the water in Thief River for several miles, but station is protected from influence of dam by rapids below.

ACCURACY.—Stage-discharge relation nearly permanent. Rating curve well defined between 0.1 second-feet and 3,800 second-feet. Gage read to hundredths twice a day. Daily discharge ascertained by applying mean daily gage heights to rating table, except during period when stage-discharge relation was affected by ice, for which period it was obtained by applying to rating table occasional gage height corrected for ice effect by means of discharge measurements, observer's notes and weather records. Open-water records excellent except those for discharge below 10 second-feet which are subject to error; winter records subject to error.

Discharge measurements of Thief River near Thief River Falls, Minn., during the year ending Sept. 30, 1917.

CLEARWATER RIVER AT RED LAKE FALLS, MINN.

LOCATION.—In sec. 22 T. 151 N., R. 44 W., at Great Northern Railway bridge at Red Lake Falls, Red Lake County, about 1½ miles above mouth and 2 miles below nearest tributary, a stream coming in from the left.

DRAINAGE AREA.—1,310 square miles.

RECORDS AVAILABLE.—June 18, 1909, to September 30, 1917, when station was discontinued.

GAGE.—Combination vertical and inclined staff gage, installed September 12, 1911, about half a mile downstream from original gage, as the building of a dam caused several feet of backwater at the old section. New gage set to read 2.23 feet when the original gage read 5.83 feet. Gage read by Leo Steinert.

DISCHARGE MEASUREMENTS.—Made from Great Northern Railway bridge or by wading about 300 feet below gage.

CHANNEL AND CONTROL.—Bed composed of sand and gravel; smooth. Control nearly permanent. Two channels at low stages, united at high stages. Banks high, wooded and not subject to overflow.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 4.4 feet April 11 (discharge, 1,080 second-feet); minimum stage recorded, 1.84 feet, August 21 (discharge 42 second-feet).

1909–1917: Maximum discharge recorded 3,990 second-feet, April 15 and 16, 1916; minimum discharge 20 second-feet, July 4, 1911.

ICE.—Stage-discharge relation seriously affected by ice.

REGULATION.—At low stages flow is affected by the Steinert dam, 600 feet above the gage. The storage at this plant is small and only a slight diurnal fluctuation is observable at gage.

ACCURACY.—Stage-discharge relation fairly permanent. Rating curve well defined between 53 and 1,160 second-feet and fairly well defined between 1,160 and 3,550 second-feet. Gage read to tenths twice a day. Daily discharge ascertained by applying mean daily gage height to rating curve, except during period when stage-discharge relation was affected by ice, for which it was ascertained by applying to rating table daily or weekly gage height corrected for effect of ice by means of discharge measurements, observer's notes, and weather records. Open-water records good except those for extreme low stages which are fair; winter records subject to error.

Discharge measurements of Clearwater River at Red Lake Falls, Minn., during the year ending Sept. 30, 1917.

ROSEAU RIVER AT CARIBOU, MINN.

LOCATION.—In sec. 34, T. 164 N., R. 45 W., at steel highway bridge in Caribou, Kittson County, 1 mile south of international boundary and 3 miles upstream from crossing of boundary line by river.

DRAINAGE AREA.—1,340 square miles.

RECORDS AVAILABLE.—April 1 to October 6, 1917, when station was discontinued.

GAGE.—Chain gage fastened to downstream handrail of bridge, 60 feet from left abutment; read by James A. McKibbin.

DISCHARGE MEASUREMENTS.—Made from highway bridge.

CHANNEL AND CONTROL.—Channel is artificial, of trapezoidal cross-section, about 100 feet wide and 10 feet deep. Bed composed of hardpan, with few scattered large boulders. Stage of zero flow, bottom of channel, gage height about 3.0 feet.

EXTREMES OF DISCHARGE.—Maximum stage recorded during period, 9.4 feet April 17 and 18 (discharge, 1,370 second-feet); minimum stage, 3.15 feet September 29 (discharge, about 4 second-feet).

ICE.—Stage-discharge relation seriously affected by ice.

DIVERSIONS.—No diversions involving storage or loss of water. A channel about 3½ miles long was dredged some years ago from a point about 4 miles above the station to a point 1 mile below. At a stage of about 6.0 feet water flows in this channel and must be measured and included in all measurements of main channel.

REGULATION.—None.

ACCURACY.—Stage-discharge relation probably permanent. Rating curve, based on two discharge measurements and by use of Kutter formula, only fairly well defined between 5 and 1,200 second-feet. Daily discharge ascertained by applying mean daily gage height to rating table, except during period when stage-discharge relation was affected by ice, for which it was obtained by applying to rating table mean daily gage height corrected for effect of ice by means of discharge measurements, observer's notes, and weather records. Records fair.

Discharge measurements of Roseau River at Caribou, Minn., during the year ending Sept. 30, 1917.

MOUSE RIVER AT MINOT, N. DAK.

LOCATION.—At Anne Street footbridge, northeast of Great Northern Railway roundhouse at Minot.

DRAINAGE AREA.—8,400 square miles.

RECORDS AVAILABLE.—May 5, 1903, to September 30, 1917.

GAGE.—Vertical staff attached to Anne Street footbridge on pier nearest left bank; vertical staff for low-stage readings on same bridge on pier nearest right bank. From 1903 to December, 1909, gage was a vertical staff similarly placed on a footbridge then existing about 20 rods above Anne Street. All gages at same datum. Gage read by Ephraim Cox.

DISCHARGE MEASUREMENTS.—Made from Anne Street bridge or by wading a few rods below the dam at the Soo Railway water tank.

CHANNEL AND CONTROL.—Bed composed of clay and silt; nearly permanent. Capacity of channel at high stages changed slightly by artificial structures or encroachments through the city. Control is a 5-foot dam of timbers and loose rock a mile below the gage, at the Soo Railway water tank; the dam raises the water at the gage about 3 feet at ordinary low stage, when the water just reaches the crest of the dam. Some water leaks through the dam, and when the discharge of the river is less than about 8 second-feet the water level falls below the crest.

Extremes of discharge.—Maximum stage during the year, 11.4 feet April 29 (discharge, 1,280 second-feet); minimum stage, 3.0 feet September 28 (discharge, 0.3 second-foot).

1903–1917: Maximum stage recorded, 21.9 feet April 20, 1904 (discharge, 12,000 second-feet); minimum stage, 1.8 feet February 28, 1913 (discharge, 0.1 second-foot).

Ice.—Stage-discharge relation only slightly affected by ice.

Diversions and regulation.—None above station, so far as known.

Accuracy.—Stage-discharge relation not permanent; slightly affected by changes in control and by ice. Rating curve used October 1 to February 28 fairly well defined; curve used March 1 to September 30 fairly well defined above 30 second-feet. Gage read to half-tenths once daily. Daily discharge ascertained by applying daily gage height to rating table. Records good, except for extreme low stages, which are fair.

Discharge measurements of Mouse River at Minot, N. Dak., during the year ending Sept. 30, 1917.

EVAPORATION AT UNIVERSITY, N. DAK.[1]

The evaporation gage at University, N. Dak., was established April 17, 1905, on a pool in a ravine called English Coulee, which runs through the campus of the University of North Dakota, immediately west of Grand Forks, N. Dak., and 2 miles west of the Minnesota boundary.

The coulee drains about 60 square miles of very level prairie. Except for brief freshets the flow in the coulee is small, varying from 1 second-foot or less to 20 second-feet. In very dry weather the water lies in pools with scarcely any perceptible flow.

A heavy galvanized-iron tank, 3 feet square and 18 inches deep, is placed in the center of an anchored raft, so that the water in the tank is at the same level as the water surface outside. The tank is filled nearly to the top, to a height precisely marked by the pointed tip of a vertical rod in the center of the tank. Once each day, after the change produced by evaporation or rainfall, the water level is restored to the original height, the precise amount of water transferred being measured with a cup of such size that one cupful of water is equivalent to 0.01 inch depth in the tank.

On the open prairie about 40 rods distant is a standard rain gage. On days of rainfall the difference (which is usually small) between the quantity measured by the rain gage and the surplus in the tank is considered the total evaporation for the day.

Observations were made usually about half an hour before sunset. The temperature of the water recorded is the observation of the water in the tank. As the tank is made of metal, it has been found that at that time of the day there is rarely a perceptible difference in temperature reading between the water within and without the tank. The temperature of the air as recorded is the mean of the readings of the standard self-recording maximum and the self-recording minimum thermometers for the preceding 24 hours.

[1] For complete description of this station and records of evaporation, rainfall, and temperature for 1905 to 1908 see U. S. Geol. Survey Water-Supply Paper 245, pp. 64-67, 1910.

The following table shows for each 10-day period during the years ending September 30, 1916 and 1917, the gross evaporation, the total rainfall, and the mean temperatures for the 10 observations of the water and of the air.

Evaporation observations at University, N. Dak., for years ending Sept. 30, 1916 and 1917.

RAINY LAKE AT RANIER, MINN.

Location.—In sec. 30, T. 71 N., R. 23 W., at foot of Rainy Lake at Ranier, Koochiching County.

Records available.—January 1, 1910, to September 30, 1917.

Gage.—Vertical staff gage at sawmill, about 500 feet above the Canadian Northern Railway bridge. Prior to June 6, 1916, a vertical staff gage in connection with a Haskell water-stage recorder on protecting crib above the Canadian Northern Railway bridge. For further information regarding location and datum of gages from which earlier records were obtained see Water-Supply Papers 325, 355, 385, and 405. Elevation of zero of gage used during present year is 488.00 feet, referred to what is known as the Minnesota and Ontario datum. The records have been reduced to a gage whose zero is at 489.00 feet, to correspond to records previously published.

Extremes of stage.—Maximum stage recorded during year, 8.56 feet October 1 and 2; minimum stage recorded, 1.9 feet September 26.

1910–1917: Maximum stage recorded, 10.99 feet June 10, 1916; minimum stage recorded, 0.85 foot March 22, 1911.

Regulation.—The stage of Rainy Lake is controlled at the dam and power plant of the Minnesota & Ontario Power Co., at International Falls, 2 miles below the outlet of the lake, water being stored during periods of high run-off and drawn off during periods of low run-off.

Cooperation.—Gage-height records furnished by the Canadian Department of Public Works.

Daily gage height, in feet, of Rainy Lake at Ranier, Minn., for the year ending Sept. 30, 1917.

a Gage not read owing to wind.

NOTE.—Gage heights referred to the same gage datum as those previously published in water-supply papers containing records for this drainage basin.

RAINY RIVER AT INTERNATIONAL FALLS, MINN.

LOCATION.—In sec. 34, T. 71 N., R. 24 W., at dam and powerhouse of Minnesota & Ontario Power Co.

DRAINAGE AREA.—14,600 square miles.

RECORDS AVAILABLE.—March 1, 1907, to September 30, 1917.

DISCHARGE.—Determined by Canadian Department of Public Works from power-house records.

EXTREMES OF DISCHARGE.—Maximum daily discharge during year, 12,700 second-feet April 13; minimum daily discharge, 1,450 second-feet December 5.

1907–1917: Maximum daily discharge, 37,300 second-feet June 7, 1916; minimum discharge, 431 second-feet April 21, 1909.

WINTER FLOW.—Determined from power-house records.

REGULATION.—Except during periods of high discharge, the flow is completely regulated at the dam and power plant of the Minnesota & Ontario Power Co. The plant is run on a 24-hour basis, so that except on Sunday the flow is fairly uniform; it is in fact much more uniform than the natural flow, use being made of the storage capacity of Rainy Lake, which has an area of about 344 square miles.

COOPERATION.—Estimates of flow through the power house are furnished by the Canadian Department of Public Works.

Daily discharge, in second-feet, of Rainy River at International Falls, Minn., for the year ending Sept. 30, 1917.

The year	12,700	1,450	9,710

NOTE.—Monthly and yearly discharge computed by engineers of the United States Geological Survey from daily-discharge record furnished by the Canadian Department of Public Works.

KAWISHIWI RIVER NEAR WINTON, MINN.

LOCATION.—In sec. 20, T. 62 N., R. 11 W., in a pond above lower dam of St. Croix Lumber Co. at Kawishiwi Falls, 500 feet above Fall Lake, 3,000 feet below Garden Lake, near western line of Lake County, 2½ miles east of Winton, St. Louis County.

DRAINAGE AREA.—1,200 square miles.

RECORDS AVAILABLE.—June 21, 1905, to June 30, 1907; and October 14, 1912, to September 30, 1917.

GAGE.—Stevens water-stage recorder installed the last part of September, 1912, at a point just above right end of dam. Well was attached to timbers bolted to the vertical rock wall of the right bank of the river. Auxiliary staff gage was also attached to one of these timbers. The gage shelter was supported by timbers which were bolted to the horizontal portion of the rock wall above all possible high water. On May 27, 1913, the Stevens was replaced by a Friez water-stage recorder. During the high water of June, 1914, the well together with the float and weight were carried away by logs. At this time a concrete well was installed by the International Joint Commission a little below the dam and outside the river channel, and connected with the pool above the dam by a pipe through the dam. The gage was repaired and again put in operation about July 1, 1914. Both water-stage recorders refer to the same datum.

DISCHARGE MEASUREMENTS.—Made from cable about 1,000 feet above gage.

CHANNEL AND CONTROL.—At the gage the river flows through a small deep pool formed by a timber dam without openings, which constitutes the control and is permanent unless the dam is destroyed or alterations are made in the crest. About 200 feet above the dam is a decided falls. Banks not overflowed in the vicinity of the gage. At the measuring section the bed of the stream is rock and bowlders; rough; current swift except at low stages.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 5.25 feet 8 p. m. June 20 (discharge, 3,140 second-feet); minimum discharge recorded 17 second-feet April 17.

1905–1907 and 1912–1917: Maximum stage recorded, 7.2 feet April 30 and May 7, 1916 (discharge, 5,370 second-feet); no flow August 24, 25, 30, 31, and September 1, 1915, August 6 and 8, 1906, and April 23, 24, and 26, 1907.

ICE.—Stage-discharge relation not seriously affected by ice; open-channel rating curve assumed applicable. The operation of the water-stage recorder is affected by ice, and the flow from December to March, which is very constant during this part of the year, is computed from weekly reading of the staff gage.

REGULATION.—The St. Croix Lumber Co. has a dam at the outlet of Garden Lake to control the level of water in that lake and store water to be used in driving logs over the stretch of rapids between Garden and Fall Lakes. This dam is capable of holding the water in Garden Lake about 7 or 8 feet above its natural level at low water before water will flow over the gates. When the water in Garden Lake is held at a high stage the elevation of water is considerably higher in Farm Lake, and it is understood that the elevation of the surface of White Iron Lake is somewhat affected by the stage of Garden Lake. During the log driving season, April to November, the water in Garden Lake is held to the elevation of the top of the gates practically all the time. In November some of the gates are opened so that the lake is drawn down to low-water stage, and remains so until spring. The St. Croix Lumber Co. has a dam at the outlet of Birch Lake, which controls its elevation, and is capable of holding the water about 5 feet above low water. This dam is left open during the winter and until the high water of the spring break-up has passed. It is then closed and the lake is held as high as possible during the summer. A number of low dams in Stony River are used for sluicing logs off rapids but create no large amount of storage back of them. Large volumes of water are allowed to pass through the sluices of the dam at the outlet of Harden Lake for a few hours at a time, at irregular intervals, when desired to drive logs from Garden Lake to Fall Lake; when the gates are closed there is only a slight flow caused by leakage through the dam. At times some of the gates are partly opened to allow passage of sufficient water to prevent flow over crest of dam.

Accuracy.—Stage-discharge relation permanent; not usually affected by ice and seldom by logs. Rating curve fairly well defined below 2,890 second-feet. Continuous record from recording gage during the open-water period; weekly gage readings during winter. Daily discharge ascertained as follows: October 1 to December 31 and April 17 to May 16 from hourly gage heights; January 1 to April 11 determined from weekly gage heights; May 20 to September 30 by the discharge integrator. Discharge estimated for brief periods when gage was not working, or record fragmentary, for periods shown in footnote to daily-discharge table. Records good except those for low stages, which are subject to error.

The following discharge measurement was made by W. G. Hoyt:

September 12, 1917: Gage height, 1.05 feet; discharge, 245 second-feet.

Daily discharge, in second-feet, of Kawishiwi River near Winton, Minn., for the year ending Sept. 30, 1917.

VERMILION RIVER BELOW VERMILION LAKE, NEAR TOWER, MINN.

Location.—In sec. 2, T. 63 N., R. 17 W., in St. Louis County, about 100 yards below dam at outlet of Vermilion Lake, 4 miles above Twomile Creek, which enters from the west, and about 18 miles across Vermilion Lake from Tower.

Drainage area.—507 square miles.

Records available.—May 17, 1911, to September 30, 1917, when station was discontinued.

Gage.—Vertical staff gage attached to a tree at the left bank; read by Mrs. A. E. Shively.

Discharge measurements.—From 1911–1913 made from a cable just below the gage; from 1914–1916 made from a boat about 1 mile below the gage.

Channel and control.—Bed composed of solid rock and large boulders. Heavy falls a short distance below the gage form permanent control; banks are not overflowed to any considerable extent.

Extremes of discharge.—Maximum stage recorded during year, 1.7 feet October 1–5 and July 5 (discharge, 397 second-feet); minimum stage recorded, 0.70 foot March 4–12, April 5–6, and September 28–30 (discharge 130 second-feet).

1911–1917: Maximum stage recorded, 3.8 feet April 29 to May 7, 1916 (discharge, 2,050 second-feet); minimum stage recorded, 0.22 foot October 1 and 2, 1914 (discharge 60 second-feet).

Ice.—Stage-discharge relation not affected by ice, owing to the heavy fall at the control section, and to the proximity to Vermilion Lake.

Regulation.—At the outlet of Vermilion Lake, a few hundred feet above the gage, is a loose rock dam which is used to raise the water surface of the lake for aid in navigation. This dam has no gates, but was repaired on July 19, 1912, thus for a period reducing the flow below normal. From April 28 to May 10, 1914, parts of the dam were removed and for some time subsequent the flow exceeded normal.

Accuracy.—Stage-discharge relation permanent. Rating curve well defined. Gage read to quarter-tenths daily; fluctuations in stage so gradual that good results are obtained from one reading a day. Daily discharge ascertained by applying daily gage height to rating table. Records good.

The following discharge measurement was made by R. B. Kilgore:

September 13, 1917: Gage height, 0.88 foot; discharge, 156 second-feet.

Daily discharge, in second-feet, of Vermilion River below Vermilion Lake, near Tower, Minn., for the year ending Sept. 30, 1917.

LITTLE FORK RIVER AT LITTLE FORK, MINN.

LOCATION.—In sec. 9, T. 68 N., R. 25 W., at lower of two highway bridges at Little Fork, Koochiching County, about 1½ miles above mouth of Beaver Brook and 2½ miles above Big Fork & International Falls Railway Bridge.

DRAINAGE AREA.—1,720 square miles.

RECORDS AVAILABLE.—June 23, 1909, to September 30, 1917, when station was discontinued.

GAGE.—Chain gage attached to new steel bridge about 100 feet above the location of the vertical staff gage which was read prior to March 5, 1917, by G. H. French and Vernon Jamison. Chain gage was set to read the same as staff gage at a gage height of 6.5 feet.

DISCHARGE MEASUREMENTS.—Made from the bridge at medium and high stages; at low stages made by wading a short distance above the bridge.

CHANNEL AND CONTROL.—Bed composed of sand, gravel, and bowlders. Banks high and not subject to overflow. Control permanent up to the summer of 1915, but during the high water in June there was a decided shift.

EXTREMES OF DISCHARGE.—Maximum stage during year, 18.7 feet 10 a. m. April 22, caused by backwater from a log jam at the railroad bridge; maximum discharge probably occurred April 23 (mean for day estimated at 4,460 second-feet); minimum discharge (estimated at 40 second-feet), February 9–20.

1909–1917: Maximum stage recorded, 37 feet April 18, 1916 (discharge, 19,300 second-feet); minimum discharge, about 40 second-feet, September 5, 1910, and February 9–20, 1917.

ICE.—Stage-discharge relation seriously affected by ice.

ACCURACY.—Stage-discharge relation permanent since high water of June, 1915 Rating curve used, well defined below 5,670 second-feet and poorly defined above that point. Gage read to quarter tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table, except for period when stage-discharge relation was affected by ice, for which it was ascertained by applying to rating table mean daily gage height corrected for effect of ice by means of discharge measurements, observers' notes, and weather records. Open-water records good; winter records subject to error.

Discharge measurements of Little Fork River at Little Fork, Minn., during the year ending Sept. 30, 1917.

UPPER MISSISSIPPI RIVER BASIN.

MISSISSIPPI RIVER AT ELK RIVER, MINN.

LOCATION.—In sec. 3, T. 121 N., R. 23 W., at highway bridge in town of Elk River, about 2,500 feet below mouth of Elk River, in Sherburne County.

DRAINAGE AREA.—14,500 square miles.

RECORDS AVAILABLE.—July 22, 1915, to September 30, 1917.

GAGE.—Chain gage bolted to the handrail of the bridge, downstream side, near right bank; read by W. H. Ebner.

DISCHARGE MEASUREMENTS.—Made from the downstream side of bridge.

CHANNEL AND CONTROL.—Bed composed of sand and gravel; control not well defined. Banks high and not subject to overflow.

EXTREMES OF DISCHARGE.—Maximum discharge occurred during period April 1–10, when gage was not read; discharge not known, although on basis of power plant records was probably about 34,000 second-feet and occurred about April 5; minimum stage 3.6 feet 7.50 a. m. September 3 and 7 p. m. September 5 (discharge, about 3,530 second-feet).

1915–1917: Maximum stage recorded during unobstructed channel, 10.8 feet April 7, 1916 (discharge, 27,000 second-feet); minimum stage recorded, 3.6 feet at 8 a. m. September 3 and 7 p. m. September 5 (discharge, about 3,530 second-feet).

ICE.—Stage-discharge relation seriously affected by ice; discharge estimated from records of discharge at Coon Rapids power plant, computed by the Minneapolis General Electric Co., allowance being made for the discharge of the Crow and Rum rivers, entering between Coon Rapids and the station.

REGULATION.—Nearest dam above the station on the Mississippi is at St. Cloud, 40 miles upstream. An observed systematic diurnal fluctuation at the gage of about 0.1 foot is doubtless due to the regulation at St. Cloud, but most of the effect of regulation is equalized before reaching the station. The flow of the river is controlled by Government dams on the upper river for the purpose of increasing the low water open season flow in the interests of navigation.

ACCURACY.—Stage-discharge relation permanent except as affected by ice. Rating curve well defined between 4,620 and 12,400 and fairly well defined between 12,400 and 26,300 second-feet. Gage read to quarter-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table except when stage-discharge relation was affected by ice, for which period it was estimated from Coon Creek power-plant records (see heading "Ice"). Open water records good; winter records subject to error.

COOPERATION.—Records of discharge at Coon Rapids power plant, upon which are based estimates of discharge during the winter months, furnished by the Minneapolis General Electric Co.

Discharge measurements of Mississippi River at Elk River, Minn., during the year ending Sept. 30, 1917.

MISSISSIPPI RIVER AT ST. PAUL, MINN.

LOCATION.—At Chicago Great Western Railway bridge near foot of Robert Street, St. Paul, 6 miles below mouth of Minnesota River, in Ramsey County.

DRAINAGE AREA.—35,700 square miles.

RECORDS AVAILABLE.—March 1, 1892, to September 30, 1917. Observations of stage begun in 1873 by United States Signal Service and continued by United States Weather Bureau. Many discharge measurements made proir to 1900 by the United States Engineer Corps.

GAGE.—Chain gage installed May 9, 1913, on the handrail, downstream side, of Chicago Great Western Railway bridge near the foot of Robert Street; read by employees of United States Weather Bureau. From 1911 to May 9, 1913, the gage was a vertical staff gage, attached to a piling on the left bank of river, about 800 feet upstream from the present gage. Prior to 1911 a vertical staff gage on the Diamond Joe Line Wharf at the foot of Jackson Street, about 400 feet below the chain gage, was used. The datum of all three gages is the same, allowance being made for the slight slope in the river between them.

DISCHARGE MEASUREMENTS.—Up to 1915 made from the Chicago, St. Paul, Minneapolis & Omaha Railway bridge, 2 miles above the station; in November, 1915, and April, 1916, measurements were made from the Chicago Great Western Railway bridge, to which the gage is attached. During 1916 and 1917 measurements have been made from the Wabasha Street highway bridge, about 1,000 feet above station.

CHANNEL AND CONTROL.—Channel somewhat shifting. Control not well defined. Banks moderately high; have not been overflowed in recent years.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 16.2 feet at 8 a. m. April 8 (discharge, 70,200 second-feet); minimum discharge occurred during the period when river was frozen over, and was probably somewhat less than 5,000 second-feet.

1892–1917: Maximum stage recorded, 18.0 feet April 6, 1897 (discharge, 80,800 second-feet); highest known discharge occurred July 22, 1867, and amounted to 117,000 second-feet. Minimum stage recorded, −0.9 foot March 22, 1896 (discharge, 1,420 second-feet).

ICE.—Stage-discharge relation seriously affected by ice; monthly mean flow generally ascertained from records obtained by United States Engineer Corps at lock and dam No. 2, below Minneapolis, allowance being made for the flow of the Minnesota River. During winter of 1916–17 records of flow past lock and dam No. 2 were not available, and determinations of flow were based on records obtained from the St. Anthony Falls Water Power Co., of Minneapolis.

REGULATION.—During extreme low water regulation of the flow through the turbines at the nearest dam in Minneapolis may cause diurnal fluctuation of stage at St. Paul. Flow is regulated by Government reservoirs on the headwaters at Lake Winnebigoshish, Leach Lake, Pokegama Lake, Sandy Lake, Pine River, and Gull Lake to increase the low-water open-season flow in the interests of navigation, but the effect of this regulation is very gradual at St. Paul.

ACCURACY.—Stage-discharge relation fairly permanent except as affected by ice. Rating curve well defined throughout. Gage read once daily to tenths, but this reading perhaps does not represent the mean daily stage accurately on account of artificial regulation at power plants in Minneapolis; occasional additional readings indicate that the error is not large. Daily discharge obtained by applying daily gage height to rating table except for period when stage-discharge relation was affected by ice, during which determinations were based on flow of Mississippi River at Minneapolis plus flow of Minnesota River. (See note regarding Ice.) Open-water records range from fair to good; winter records subject to error.

COOPERATION.—Gage-height record furnished by United States Weather Bureau. Data upon which mean monthly flow during winter periods have been based furnished by United States Corps of Engineers.

Discharge measurements of Mississippi River at St. Paul, Minn., during the year ending Sept. 30, 1917.

[Made by Soulé and Kilgore.]

CROW WING RIVER AT MOTLEY, MINN.

LOCATION.—Near north border of sec. 18, T. 133 N., R. 31 W., at highway bridge in Motley, Cass County, about a quarter of a mile north of Northern Pacific Railway station and 2 miles above mouth of Long Prairie River, the nearest tributary.

DRAINAGE AREA.—2,140 square miles.

RECORDS AVAILABLE.—June 10 to November 30, 1909; April 17, 1913, to September 30, 1917, when station was discontinued. Records for 1909 consist of discharge measurements and gage heights only.

GAGE.—Chain gage attached to upstream handrail of bridge near right bank, read by S. W. Jacobs. Prior to July 21, 1916, gage was a staff gage in two sections, the lower section attached to an old log bulkhead which constituted the abutment of a former bridge, and was about 20 feet above the upstream edge of the bridge, at the left bank; upper section was attached to an old piling just above the lower section.

DISCHARGE MEASUREMENTS.—Made from upstream side of the bridge.

CHANNEL AND CONTROL.—Bed composed of sand and gravel; fairly permanent. Banks not subject to overflow.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 13.2 feet at 6 p. m. April 5 when stage-discharge relation was affected by ice (mean discharge for day estimated at 3,600 second-feet); minimum open-water stage recorded, 5.70 feet August 28 and 29 (discharge, about 270 second-feet).

1913–1917: Maximum stage recorded, 11.5 feet April 5 and 6, 1916 (discharge, 9,440 second-feet); minimum open-water stage recorded, 5.70 feet August 28 and 29, 1917 (discharge, about 270 second-feet).

ICE.—Stage-discharge relation seriously affected by ice.

REGULATION.—Nearest dam above station is at outlet of Lower Crow Wing Lake, about 67 miles above Motley; regulation at this point has very little effect at the gage.

ACCURACY.—Stage-discharge relation fairly permanent. Rating curve well defined between 450 and 4,790 second-feet. Gage read to quarter-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to the rating table except for period when stage-discharge relation was affected by ice for which it was obtained by applying to rating table mean daily gage heights corrected for effect of ice by means of discharge measurements, observer's notes, and weather records. Open-water records good; winter records fair.

Discharge measurements of Crow Wing River at Motley, Minn., during the year ending Sept. 30, 1917.

LONG PRAIRIE RIVER NEAR MOTLEY, MINN.

LOCATION.—On west line of sec. 19, T. 133 N., R. 31 W., at highway bridge 1 mile south of Motley and 2 miles above mouth of river, in Morrison County.

DRAINAGE AREA.—973 square miles.

RECORDS AVAILABLE.—June 10, 1909, to September 30, 1917, when station was discontinued.

GAGE.—Chain gage attached to downstream handrail of bridge, near middle of stream; read by Mrs. Clem Thompson. Prior to August 9, 1916, the gage was a staff attached to an overhanging stump on right bank of the river, about 100 yards above bridge.

DISCHARGE MEASUREMENTS.—Made from downstream side of highway bridge to which gage is attached; low-stage measurements made by wading a short distance above gage.

CHANNEL AND CONTROL.—Bed composed of light gravel; practically permanent, affected by aquatic plants during portion of the year; left bank low, subject to overflow; right bank high and not subject to overflow.

EXTREMES OF DISCHARGE.—Maximum stage recorded when control was unobstructed, 9.00 feet at 8.30 a. m. April 6 (discharge, 2,540 second-feet); minimum discharge 105 second-feet March 1–11.

1909–1917: Maximum stage during period, 15.0 feet, April 5, 1916 determined by leveling from flood marks (estimated discharge, 4,280 second-feet, allowance being made for backwater). A discharge of 39 second-feet was measured by current meter on February 27, 1914; absolute minimum probably about 30 second-feet.

ICE.—Stage-discharge relation seriously affected by ice.

ACCURACY.—Stage-discharge relation probably permanent except as affected by ice and growth of aquatic plants. Rating curve used October 1 to July 30 fairly well defined between 78 and 1,730 second-feet; extension above 1,730 second-feet determined from area and mean velocity curves. Gage read to half-tenths twice daily. Daily discharge ascertained by applying mean daily gage heights to rating table; discharge August 1 to September 30, determined by shifting-control method owing to obstruction of the channel by vegetation. Discharge for periods when stage-discharge relation was affected by ice ascertained by applying to rating table gage height corrected for backwater by means of discharge measurements, observer's notes, and weather records. Open-water records fair; winter records subject to error.

Discharge measurements of Long Prairie River near Motley, Minn., during the year ending Sept. 30, 1917.

ELK RIVER NEAR BIG LAKE, MINN.

LOCATION.—In sec. 23, T. 33 N., R. 27 W., at highway bridge 4 miles east of Big Lake, Sherburne County, three-fourths of a mile north of Bailey station on Northern Pacific and Great Northern railways, half a mile above Tebbetts Brook, and 4 miles below mouth of St. Francis River.

DRAINAGE AREA.—615 square miles.

RECORDS AVAILABLE.—April 15, 1911, to September 30, 1917, when station was discontinued.

GAGE.—Vertical staff gage attached to upstream edge of left abutment; read by Michael Tracy. Prior to April 7, 1916, the gage was a staff gage attached to a piling about 10 feet above the upstream edge of the bridge, near the right bank of the river.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge or by wading.

CHANNEL AND CONTROL.—Bed composed of sand and light gravel. Just below the gage is a slight rapids which constitutes the control at medium and low stages, and at which the bed consists of heavier gravel and cobblestones and is fairly permanent. From July to October the channel is usually obstructed by aquatic plants, which cause considerable backwater, that increases as the summer advances and reaches a maximum some time in September. No obstruction due to aquatic plants during the period April to September, 1917, due apparently to the change in control section. Right bank high and not subject to overflow; left bank subject to overflow at a stage of about 9 feet, and some of the water cuts across a point formed by a loop in the river, and does not pass under the bridge.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 6.88 feet April 6 (discharge, 2,850 second-feet); minimum discharge about 75 second-feet January 24, 25, 28, and 29.

1911–1917: Maximum stage recorded, 10 feet at 6.30 p. m. May 7, 1912 (discharge, 5,100 second-feet); minimum open-water stage recorded during period, 0.22 foot July 16, 1911 (discharge, 43.4 second-feet, measured by current meter); a discharge of 39 second-feet was measured by current meter on January 27, 1912.

ICE.—Stage-discharge relation seriously affected by ice.

ACCURACY.—Stage-discharge relation not permanent; change in control occurred about April 4 and 5 caused by breaking of ice jam with flood stage. Rating curve used October 1 to April 4, well defined throughout; curve used April 5 to September 30 well defined between 124 and 2,930 second-feet. Gage read to quarter-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table except for period when stage-discharge was affected by aquatic plants, for which it was ascertained by applying to rating table mean daily gage height corrected for effect of backwater by means of discharge measurements, and for winter period by observer's notes and weather records. Records good for period when channel was unobstructed, winter records fair.

Discharge measurements of Elk River near Big Lake, Minn., during the year ending Sept. 30, 1917.

CROW RIVER AT ROCKFORD, MINN.

LOCATION.—In sec. 29, T. 119 N., R. 24 W., at highway bridge at Rockford, about 400 feet below dam (not in use at present), about one-third mile below "Soo" Railway bridge and about a mile below junction of north and south branches. Between junction and station are outlets of Rebecca Lake and Lake Sarah, both very small streams.

Records available.—June 4, 1909, to September 30, 1917, when station was discontinued.

Drainage area.—2,520 square miles.

Gage.—Vertical staff gage attached to a piling a few feet above the right end of the bridge; read by George W. Florida.

Discharge measurements.—Made from the bridge or by wading about 600 feet below the gage.

Channel and control.—For most part bed of stream is composed of heavy gravel; practically permanent. Banks are not overflowed except during extreme floods.

Extremes of discharge.—Maximum stage recorded during year, 14.5 feet at 6 p. m. April 7, and 7 a. m. April 6 (discharge, 8,500 second-feet); minimum discharge, 75 second-feet (measured by current meter February 27).

1909–1917: Maximum stage recorded, 15.9 feet at 6 p. m. April 2 and 7 a. m. April 3, 1916 (discharge, 10,600 second-feet); minimum open-water stage recorded, 4.55 feet January 29 and February 5, 1911 (discharge, 34 second-feet); true minimum, probably about 30 second-feet, occurred in February, 1915.

Ice.—Stage-discharge relation seriously affected by ice. Prior to the winter of 1911–12, little ice formed at the control, and the open-water rating curve was applicable throughout the year. Before the dam just above the station was destroyed the temperature of the large body of water back of the dam was considerably above freezing, and the water did not freeze quickly when released; but since the destruction of the dam natural conditions exist and ice forms.

Regulation.—On the North, Middle, and South forks of Crow River there are seven power plants with small storage, but the regulation at the various points is so slight that no appreciable effect is observed at the gage. The dam immediately above the gage was partly destroyed May 31, 1911, and has not since been repaired.

Accuracy.—Stage-discharge relation practically permanent except as affected by ice. Rating curve well defined between 90 and 10,700 second-feet. Gage read to hundredths twice daily. Owing to effect of ice on gage there is some question as to the gage datum used during the winter and early spring. Daily discharge ascertained by applying mean daily gage height to rating table except during period when stage-discharge relation was affected by ice, for which it was roughly estimated from discharge measurements and observer's notes. Open-water records good except for flood stages, for which they are fair; winter records roughly approximate.

Discharge measurements of Crow River at Rockford, Minn., during the period Oct. 1, 1916, to Oct. 4, 1917.

MINNESOTA RIVER NEAR MANKATO, MINN.

LOCATION.—In sec. 14, T. 108 N., R. 27 W., in Blue Earth County, at Sibley Park, 2 miles above center of Mankato and 1,000 feet below mouth of Blue Earth River.

DRAINAGE AREA.—14,600 square miles.

RECORDS AVAILABLE.—May 20, 1903 to September 30, 1917.

GAGE.—Chain gage on right bank of river, about 1,000 feet below mouth of Blue Earth River; read by Clarence Staley, observer for United States Weather Bureau. The gage support is a substantial cantilever structure, supported by two heavy posts resting in concrete footings, constructed and maintained by the United States Engineer Corps.

DISCHARGE MEASUREMENTS.—Made from highway bridge in center of Mankato, by wading a short distance below gage, or at extreme high stages, by boat near gage.

CHANNEL AND CONTROL.—Bed composed of sand and light gravel; fairly permanent except during high stage; banks moderately high and not subject to overflow except at stages above gage height of 15 feet. Control not well defined.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 15.8 feet April 5 (discharge, about 26,900 second-feet); minimum discharge 248 second-feet measured by current meter February 28.

1903–1917: Maximum stage recorded, 21.2 feet June 26, 1908 (discharge, 43,800 second-feet); minimum stage recorded, 0.5 foot August 31, September 1 and 2, 1911 (discharge, 89 second-feet). The highest known stage of this river occurred in 1881, and is shown in Mankato by a well-marked line which was approximately 27 feet above the zero of the present gage (discharge estimated 65,000 second-feet).

ICE.—Stage-discharge relation seriously affected by ice.

REGULATION.—The nearest dam on Minnesota River is at Minnesota Falls, 140 miles upstream. A dam on Blue Earth River at Rapidan, a few miles above the mouth, controls the flow of that river, which is about 20 per cent of that at the Mankato station, and produces considerable daily fluctuation at the gage, amounting at times to more than 1 foot.

ACCURACY.—Stage-discharge relation not permanent; change in control section probably occurred during high water of June or was gradual between June and September. Rating curve used October 1 to June 15, well defined throughout; curve used June 16 to September 30 poorly defined. Gage read to tenths once daily. This reading does not represent accurately the mean daily stage on account of fluctuation caused by artificial regulation. Daily discharge ascertained by applying the daily gage height to rating table except for period when stage-discharge relation was affected by ice, for which it was ascertained by applying to rating table daily gage height corrected for effect of ice by means of discharge measurements, observer's notes, and weather records. Open-water records fair; winter records poor.

COOPERATION.—Gage-height record furnished by United States Weather Bureau.

Discharge measurements of Minnesota River near Mankato, Minn., during the year ending Sept. 30, 1917.

CHIPPEWA RIVER NEAR WATSON, MINN.

LOCATION.—On line between secs. 10 and 15, T. 118 N., R. 41 W., at highway bridge about 2½ miles northeast of Watson, Chippewa County, about 2 miles below mouth of Dry Weather Creek and 10 miles above mouth of river.

DRAINAGE AREA.—1,940 square miles.

RECORDS AVAILABLE.—Apr. 27, 1910, to September 30, 1917, when station was discontinued. From July 6 to September 17, 1909, four discharge measurements were made at the station.

GAGE.—Chain gage attached to downstream side of the bridge, near left bank of river; read by Clifford Bonde.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge to which gag[e] is attached or by wading a short distance above gage.

CHANNEL AND CONTROL.—Bed consists partly of sand and light gravel and partly clay; shifts somewhat. The right bank slopes gradually, and the width of the stream increases rapidly as stage increases from 10 to 12 feet.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 17.86 feet April 4 (discharge, assuming there was no backwater from ice jams, about 9,600 second-feet); minimum stage recorded 4.55 feet September 5 (discharge 21 second-feet).

1910–1917: Maximum stage recorded April 4, 1917; minimum stage recorded during open-water periods 3.90 feet August 7, 8, and 9, 1910 (discharge, 5 second-feet). A discharge of 1.7 second-feet was measured by current meter February 9, 1912.

ICE.—Stage-discharge relation seriously affected by ice.

ACCURACY.—Stage-discharge relation not permanent; change occurred probably during the high water of April and May. Rating curve used October 1 to November 11, well defined between 358 and 4,250 second-feet; curve used April 6 t[o] September 30, poorly defined throughout. Gage read to hundredths once daily; observations discontinued during winter. Daily discharge ascertained by applying gage height to rating table. Records fair.

Discharge measurements of Chippewa River near Watson, Minn., during the year ending Sept. 30, 1917.

ST. CROIX RIVER AT SWISS, WIS.

LOCATION.—In sec. 33, T. 42 N., R. 15 W., at highway bridge near post office of Swiss, Burnett County, about 2 miles above point where St. Croix River becomes boundary line between Wisconsin and Minnesota, 10 miles northeast of Danbury, Minn., on Minneapolis, St. Paul & Sault Ste. Marie Railway. Namakagon River enters from left about 3½ miles above station.

DRAINAGE AREA.—1,550 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale: 1 inch=6 miles).

RECORDS AVAILABLE.—March 20, 1914, to September 30, 1917.

GAGE.—Cast-iron staff gage bolted to concrete pier at left end of bridge; read by Capt. Richard Goldschmidt.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge.

CHANNEL AND CONTROL.—Gravel, smooth; acquatic plants during summer months may cause a small amount of backwater at the gage. Right bank high and not subject to overflow; left bank of medium height and may possibly be overflowed during extremely high water.

EXTREMES OF DISCHARGE.—Maximum stage recorded during the year, 3.05 feet at 6.40 a. m., July 21 (discharge, 2,840 second-feet); minimum discharge estimated at 710 second-feet February 22.

1914–1917: Maximum stage recorded, 6.73 feet at 6.45 a. m., April 22, 1916 (discharge, 8,480 second-feet); minimum discharge, February 22, 1917.

ACCURACY.—Stage-discharge relation practically permanent except as affected by backwater from grass October 1–19, and by ice November 15 to April 4. Two rating curves used during year, applicable as follows: October 1 to April 4, fairly well defined between 1,000 and 7,500 second-feet; April 5 to September 30, fairly well defined between 850 and 7,500 second-feet. Gage read to quarter-tenths twice daily. Daily discharge, except as noted below, ascertained by applying mean daily gage height to rating table; discharge October 1–29 determined by shifting-control method, owing to backwater from grass; discharge November 15 to April 4, estimated, because of ice, from discharge measurements, observer's notes, and weather records. Open-water records good; winter records fair.

Discharge measurements of St. Croix River at Swiss, Wis., during the year ending Sept. 30, 1917.

ST. CROIX RIVER NEAR ST. CROIX FALLS, WIS.

Location.—In sec. 18, T. 34 N., R. 18 W., at power plant of Minneapolis General Electric Co., on Wisconsin side of St. Croix River, near St. Croix Falls, Polk County, Wis., about 50 miles above confluence of St. Croix and Mississippi rivers near Hastings, Minn. Apple River, draining an area wholly in Wisconsin, enters from the left about 20 miles below the station; Snake River, draining an area in Minnesota, enters from the right, about 35 miles above the station.

Drainage area.—5,930 square miles.

Records available.—January 10, 1902, to June 30, 1905; January 1, 1910, to September 30, 1917. Data for 1903 published in Water-Supply Paper No. 98, pages 176–177, under "St. Croix River near Taylors Falls, Minn."

Discharge.—Determinations of discharge based on kilowatt output of dynamo and exciters plus flow over dam and spillway, considered as a weir.

Extremes of discharge.—Maximum daily discharge during year, 17,700 second-feet April 5; minimum daily discharge 1,120 second-feet January 1, 1917.

1902–1905 and 1910–1917: Maximum daily discharge 35,100 second-feet April 23, 1916; minimum daily discharge 75 second-feet July 17, 1910. Minimum discharge caused by regulation.

Regulation.—Low-water flow controlled by operation of gates of power plant and by storage and release of water at Never's dam several miles upstream.

Accuracy.—Records have not been checked nor have any discharge measurements been made by engineers of the United States Geological Survey; probably reliable.

Cooperation.—Records furnished by the Minneapolis General Electric Co.

Daily discharge, in second-feet, of St. Croix River near St. Croix Falls, Wis., for the year ending Sept. 30, 1917.

NOTE.—Monthly and yearly discharge computed by engineers of the U. S. Geological Survey from records of daily discharge furnished by the Minneapolis General Electric Co.

NAMAKAGON RIVER AT TREGO, WIS.

LOCATION.—In sec. 35, T. 40 N., R. 12 W., at Chicago & Northwestern Railway bridge at Trego, Washburn County, about 20 miles above confluence of Namakagon and Totogatic rivers.

DRAINAGE AREA.—420 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale: 1 inch=6 miles).

RECORDS AVAILABLE.—March 11, 1914, to September 30, 1917.

GAGE.—Enameled staff fastened to retaining wall, left bank of river, just above railroad bridge; read by G. E. Krenz.

DISCHARGE MEASUREMENTS.—Made from lower chords of railroad bridge.

CHANNEL AND CONTROL.—Bed composed of coarse gravel; free from vegetation. Banks medium high and not subject to overflow. Small island downstream, with rapids on either side, forms the control; channel fairly permanent.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 2.3 feet April 4 (discharge, 803 second-feet); minimum discharge estimated, 235 second-feet December 19.

1914–1917: Maximum stage recorded, 3.0 feet April 23, 1916 (discharge, 1,330 second-feet); minimum discharge estimated, 235 second-feet December 19, 1916.

ACCURACY.—Stage-discharge relation permanent, except for ice effect. Rating curve well defined between 330 and 1,330 second-feet; extended below 330 second-feet by estimation. Gage read to half-tenths once daily. Daily discharge ascertained by applying daily gage height to rating table except for period in which stage-discharge relation was affected by ice, for which it was obtained by applying to rating table daily gage heights corrected for ice effect by means of discharge measurements, observer's notes, and weather records. Open-water records good; winter records fair.

Discharge measurements of Namakagon River at Trego, Wis., during the year ending Sept. 30, 1917.

[Made by R. B. Kilgore.]

KETTLE RIVER NEAR SANDSTONE, MINN.

LOCATION.—Near south line of sec. 34, T. 43 N., R. 20 W., at quarries of Barber Asphalt Co. at Banning, 3 miles above Sandstone, Pine County.

DRAINAGE AREA.—825 square miles.

RECORDS AVAILABLE.—October 18, 1908, to December 7, 1916, when station was discontinued.

GAGE.—Vertical staff in two sections, bolted to rock wall on right bank of river, about 300 feet above the steam power house of the Barber Asphalt Co.; read by F. L. Betts.

DISCHARGE MEASUREMENTS.—Made from highway bridge about a mile above gage.

EXTREMES OF DISCHARGE.—1908–1916: Maximum stage recorded, 7.7 feet, April 24, 1916 (discharge, 10,600 second-feet); minimum stage recorded, 0.7 foot, November 30, 1912 (discharge about 12 second-feet).

ICE.—Stage-discharge relation seriously affected by ice; not, however, for so long a period as at most gaging stations in the same latitude, owing to the fact that a decided rapids about 50 feet below the gage constitutes the control. The published records of winter discharge to which the open-channel rating curve is not applicable, have been based on gage readings and a comparison of the records with those for Snake River.

ACCURACY.—Stage-discharge relation permanent except as affected by ice. Rating curve well defined from 52 to 5,940 second-feet; above 5,940 second-feet it is an extension. Gage read daily to quarter-tenths. Daily discharge ascertained by applying daily gage height to rating table. Records good.

Daily discharge, in second-feet, of Kettle River near Sandstone, Minn., for the period Oct. 1 to Dec. 7, 1917.

SNAKE RIVER NEAR PINE CITY, MINN.

LOCATION.—In sec. 26 T. 39 N., R. 21 W., at Changwatana power station of Eastern Minnesota Power Co., 600 feet below dam belonging to that company, 3,500 feet below Cross Lake, 2 miles below Pine City, and about 11 miles above the mouth, in Pine County.

DRAINAGE AREA.—915 square miles.

RECORDS AVAILABLE.—June 26, 1913, to September 30, 1917, when station was discontinued.

GAGE.—Staff gage attached to stone retaining wall in front of the power plant on the left bank of the river; read by E. W. Barnum, and other employees of the Eastern Minnesota Power Co. This gage is used for determining the flow over the dam during periods when all of the flow does not pass through the turbines.

DISCHARGE MEASUREMENTS.—Made by wading or from bridge about 1,800 feet above the gage.

CHANNEL AND CONTROL.—Bed of stream rock and heavy gravel; banks in vicinity of gage high and not likely to be overflowed. Zero flow at stage 0.2 foot.

DETERMINATION OF FLOW.—Flow determined by adding to the flow through the turbines the flow over the crest of the dam as obtained from readings of the staff gage. The flow through the turbines is computed from hourly records of the gate openings and head.

Extremes of discharge.—Maximum daily discharge, 4,580 second-feet, April 6; minimum daily discharge, 59 second-feet, January 28 and March 4.

1913–1917: Maximum discharge 7,315 second-feet, April 25, 1916; minimum discharge 33 second-feet, February 11, 1914.

Winter flow.—All water goes through the wheels in winter; flow estimated from gate openings and head.

Regulation.—Power plant at the station is operated with a varying load for light and power, causing daily and weekly fluctuations in discharge at low stages. No appreciable regulation above plant.

Accuracy.—When the flow is about 200 second-feet or less, the greater part of it passes through the power plant and is estimated from turbine gate openings and head on the wheels, an hourly record of which is kept at the plant. The results of this determination can be considered only fair. As the volume of flow increases a larger portion passes by the plant as waste, at very high stages by far the greater part of the discharge is waste; this part of the discharge is determined from gage heights read from a gage in the river opposite the power plant. Stage-discharge relation for river gage permanent. Rating curve well defined throughout. Gage read to hundredths every four hours. Daily discharge ascertained by applying each gage height to the rating table, and taking the mean of the six determinations of discharge. Records of total flow at the station range from fair for low stages to excellent for high stages.

Cooperation.—The hourly records of gate openings of the turbines and head, and reading of the river gage are furnished by the Eastern Minnesota Power Co. Records for last part of current year computed by the employees of the company by use of rating curves prepared by the engineers of the Survey.

Daily discharge, in second-feet, of Snake River near Pine City, Minn., for the year ending Sept. 30, 1917.

APPLE RIVER NEAR SOMERSET, WIS.

LOCATION.—In sec. 21, T. 31 N., R. 19 W., St. Croix County, at power plant of St. Croix Power Co., 3½ miles below Somerset and 2 miles above mouth of river.

DRAINAGE AREA.—550 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale: 1 inch=6 miles).

RECORDS AVAILABLE.—January 1901, to September 30, 1917.

GAGE.—Vertical staff gage; readings not used in determination of flow.

DISCHARGE.—The discharge of the turbines in second-feet corresponding to the number of kilowatts is determined for each hour during the day from a record of the number of wheels in operation and the load; the sum of the discharge divided by 24 gives the average discharge through the turbines. To this quantity is added the leakage through the average number of wheels idle each day, the sum giving the daily flow through the power house. Water is seldom wasted over the spillway of the dam, but when it is so wasted the quantity is computed from weir formulas and added to the flow through the plant. There is a constant leakage through the gate and flashboards amounting to 3 second-feet. This quantity has not been taken into consideration in computing the published records.

EXTREMES OF DISCHARGE.—Maximum daily discharge during year, 966 second-feet, April 6; minimum daily discharge, 62 second-feet October 26.

1904–1917: Maximum daily discharge, 2,280 second-feet in June, 1905; minimum daily discharge, 38 second-feet May 10, 1910. Minimum discharge caused by regulation. Records of maximum and minimum discharge, 1901–1903, not available.

REGULATION.—There are a number of power plants on Apple River above the station. The pondage of these plants is small, and though the daily flow may be controlled to some extent the mean monthly flow probably corresponds closely to the natural flow.

ACCURACY.—In June, 1914, a series of current-meter measurements were made by the Wisconsin Railroad Commission and United States Geological Survey, and a rating curve for the tailrace was developed. Twelve tests were then run with different wheels and loads. It was found that the discharge as determined by the current meter and the discharge as computed by the company agreed very closely, the percentage difference for the 12 tests ranging from −6.4 per cent to +1.8 per cent, with an average of −2.0 per cent; the discharge as determined by the company being 2 per cent less than that determined by the current meter.

COOPERATION.—Records furnished by the St. Paul Gas Light Co., of St. Paul, Minn., F. L. Cross, general manager.

No discharge measurements were made at this station during the year.

Daily discharge, in second-feet, of Apple River near Somerset, Wis., for the year ending Sept. 30, 1917.

KINNIKINNIC RIVER NEAR RIVER FALLS, WIS.

Location.—In sec. 18, T. 27 N., R. 19 W., at Clifton Hollow Bridge, a quarter of a mile downstream from dam of Clifton Falls Power Co., 2 miles above mouth of river and 7 miles downstream from River Falls, Pierce County.

Drainage area.—170 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale: 1 inch=6 miles).

Records available.—October 23, 1916, to September 30, 1917.

Gage.—Gurley graph water-stage recorder, in a wooden well fastened to downstream side of right-hand cushing bridge pier.

Discharge measurements.—Made from bridge or by wading.

Channel and control.—Bed composed of rather heavy gravel and sand; control is head of small rapids 150 feet below the gage. High water will wash out and fill in this control section, causing small changes.

Extremes of discharge.—Maximum stage recorded during year, 5.66 feet 4.30 p. m. March 27 (discharge, about 1,900 second-feet); minimum stage recorded, 1.7 feet (discharge, about 15 second-feet), occurred several times following complete shutdown. The maximum is about the natural maximum; minimum caused by regulation at the power house.

Ice.—Stage-discharge relation affected to some extent by ice.

Regulation.—The daily flow is regulated almost completely by the Clifton power dam just above the station. There are three dams in River Falls which may also have some effect on the daily flow. The storage at these dams is, however, relatively small, and the monthly flow is considered to be nearly the normal flow.

Accuracy.—Stage-discharge relation not permanent. Three rating curves used as follows: October 22 to March 25, well defined between 0 and 120 second-feet; March 26 to July 18, fairly well defined between 15 and 400 second-feet, extended and subject to error above and below these limits; July 19 to September 30, 1917, poorly defined throughout. Continuous gage record obtained by recording gage, except during a portion of January and February, when gage well was frozen. Daily discharge ascertained by means of discharge integrator, except during last part of January and February, when it was estimated. Open-water records good, except those for high water, which are fair; winter records subject to some error.

Discharge measurements of Kinnikinnic River near River Falls, Wis., during the years ending Sept. 30, 1916 and 1917.

CHIPPEWA RIVER AT BISHOP'S BRIDGE, NEAR WINTER, WIS.

Location.—In sec. 23, T. 39 N., R. 6 W., at highway bridge 3 miles downstream from East Fork of Chippewa River (coming in from the left) and 4 miles by road northwest of Winter, Sawyer County.

Drainage area.—775 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

Records available.—February 23, 1912, to September 30, 1917.

Gage.—Chain gage fastened to highway bridge used since May 23, 1916; read by John Edburg. Gages previously used as follows: February 23, 1912, to January 27, 1914, a wooden staff gage fastened to a wooden pier on right bank just above bridge; datum 3.44 feet above that for chain gage; January 27, 1914, to May 28, 1916, a vertical cast-iron staff gage fastened to same pier; datum same as for chain gage.

Discharge measurements.—Made from downstream side of highway bridge.

Channel and control.—Bed composed of gravel; free from vegetation and not subject to shift. Control is at head of rapids about 1,000 feet below gage; practically permanent. One channel at all stages. Banks not subject to overflow.

Extremes of discharge.—Maximum stage recorded during year, 7.23 feet at 9 a. m. April 22 (discharge, 3,020 second-feet); minimum discharge estimated at 175 second-feet February 17.

1913–1917: Maximum stage recorded, 9.56 feet April 22, 1916 (discharge, 6,940 second-feet); minimum discharge (estimated) February 17, 1917.

Regulation.—Flow modified to some extent by operation of storage reservoir in sec. 14, T. 41 N., R. 6 W., about 16 miles above station. Reservoir has a capacity of 550,000,000 cubic feet and is used in connection with reservoirs on upper Flambeau River for regulating flow of Chippewa River.

Accuracy.—Stage-discharge relation permanent except as effected by ice during winter period and by logs during a portion of April and May. Rating curve well defined between 270 and 6,820 second-feet. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table, except for period in which stage-discharge relation was affected by ice, for which it was obtained by applying to the rating table daily gage height corrected for ice effect by means of discharge measurements, observer's notes, and weather records; discharge for periods of April and May, when logs were present, interpolated. Open-water records excellent except those for April and May which are fair; winter records good.

Discharge measurements of Chippewa River at Bishop's Bridge, near Winter, Wis., during the year ending Sept. 30, 1917.

[Made by R. B. Kilgore.]

CHIPPEWA RIVER NEAR BRUCE, WIS.

LOCATION.—In sec. 4, T. 35 N., R. 7 W., at Minneapolis, St. Paul & Sault Ste. Marie Railway bridge 1 mile east of Bruce, Rush County. Thornapple River enters from the left immediately above the station, and Flambeau River from the left about 21 miles below.

DRAINAGE AREA.—1,600 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

RECORDS AVAILABLE.—December 31, 1913, to September 30, 1917.

GAGE.—Chain gage, attached to downstream side of Minneapolis, St. Paul & Sault Ste. Marie Railway bridge; read by H. C. Gardner.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge.

CHANNEL AND CONTROL.—Bed composed of sand and small gravel; free from vegetation; first and second channels from the west fairly permanent; third channel nearest east bank has a tendency to fill during low stages with sand worked in by Thornapple River. Flow except during extreme high stages is confined within the banks.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 8.05 feet April 21 (discharge, 7,060 second-feet); minimum discharge estimated 310 second-feet during January and February.

1910–1917: Maximum stage recorded: 12.3 feet at 5.45 p. m., April 22, 1916 (discharge 13,400 second-feet); minimum discharge, about 310 second-feet during January and February, 1917

ICE.—Stage-discharge relation affected by ice.

REGULATION.—Flow modified to some extent by reservoir on the West Fork of Chippewa River, in sec. 14, T. 41 N., R. 6 W. Reservoir has a capacity of 550,000,000 cubic feet, and is used in connection with reservoirs on upper Flambeau River for the purpose of regulating the flow of Chippewa River. No diurnal fluctuation is observed.

ACCURACY.—Stage-discharge relation not permanent; affected by ice during winter periods and changes caused by shifting control during periods of low water. Rating curves poorly defined. Gage read to quarter tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table, except for the period in which stage-discharge relation was affected by ice, for which periods it was obtained by applying to rating table mean daily gage height corrected for ice effect by means of discharge measurements, observer's notes, and weather records. Open-water records fair; winter records subject to error.

Discharge measurements of Chippewa River near Bruce, Wis., during the year ending Sept. 30, 1917.

CHIPPEWA RIVER AT CHIPPEWA FALLS, WIS.

LOCATION.—In SE. ¼ sec. 6, T. 28 N., R. 8 W., at highway bridge at Chippewa Falls, Chippewa County, 2,500 feet below mouth of Duncan Creek, coming in from the right.

DRAINAGE AREA.—5,600 square miles.

Records available.—June 22, 1888, to September 30, 1917. The gage was originally established by the Chippewa Lumber & Boom Co., which has kept a continuous record since 1889. Since 1904 the United States Weather Bureau has obtained gage readings during the flood season of each year. On June 1, 1906, the United States Geological Survey began making discharge measurements and maintaining gage readings.

Gage.—On July 27, 1916, a Gurley graph water-stage recorder replaced Friez water-stage recorder which was installed January, 1914, on web between cushing piers supporting first right-hand span and about 10 feet upstream from the gage formerly used by United States Weather Bureau; gage referred to the original datum.

Discharge measurements.—Made from downstream side of bridge or by wading.

Channel and control.—Heavy gravel; fairly permanent; both banks high and are rarely overflowed.

Extremes of stage.—Maximum stage recorded during year, 8.32 feet at 12 a. m., April 23 (discharge 24,900 second-feet); minimum discharge estimated 40 second-feet February 4; on this date all gates and other openings in the Wissota plant of the Wisconsin & Minnesota Light & Power Co. were closed, the discharge of 40 second-feet being the inflow between the dam and the station.

1888–1917: Maximum stage recorded, 26.03 feet December 6, 1896. September 10, 1884, a stage of 26.94 feet was reached; discharge not estimated. Minimum discharge recorded February 4, 1917.

Ice.—Stage-discharge relation seriously affected by ice.

Regulation.—From October to January 15 little fluctuation was caused by the operation of power plant about half a mile above gage. Considerable fluctuation was, however, caused by the operation of larger plants above, notably the plant of the Burnett Falls Manufacturing Co., at Cornell, Wis. Beginning about January 15 operation was started at the Wissota plant of the Wisconsin & Minnesota Light & Power Co. The pond was filled during January and February and operation of the wheels was begun about February 15. After this date flow during medium and low stage is controlled by this plant.

Accuracy.—Stage-discharge relation practically permanent. Rating curve well defined between 530 and 56,200 second-feet; below 530 second-feet poorly defined. Operation of water-stage recorder was satisfactory throughout the year. Except for periods when stage-discharge relation was affected by ice, daily discharge October 1 to May 11 ascertained by applying to rating table, mean daily gage height obtained by planimeter from gage-height graph; discharge May 12 to September 30 obtained with the discharge intergrator. Discharge during periods when stage-discharge relation was affected by ice November 18–24, December 14 to April 5 ascertained by applying to rating curve mean daily gage height corrected for the effect of ice by means of discharge measurements, observer's notes, and weather records, and to some extent on computations of flow through the Wissota dam. Open-water records good; winter records roughly approximate.

Discharge measurements of Chippewa River at Chippewa Falls, Wis., during the year ending Sept. 30, 1917.

FLAMBEAU RIVER NEAR BUTTERNUT, WIS.

Location.—In NW. ¼ SE. ¼ sec. 33, T. 41 N., R. 1 E., Ashland County, 6 miles southeast of Butternut and 7 miles upstream from Park Falls.

Drainage area.—660 square miles (measured on map issued by Wisconsin Geological & Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

Records available.—July 30, 1914, to September 30, 1917.

Gage.—Chain gage supported by built-up cantilever attached to posts set in the right bank of the river, installed May 26, 1916; read by Miss Mathilda Schulz. Vertical staff gage at same site and datum was used from July 30, 1914, until taken out by ice in spring of 1916.

Discharge measurements.—Made from a cable 1,500 feet downstream from gage.

Channel and control.—Bed at gage composed of mud and rock. Left bank is low and subject to overflow; right bank slopes back gradually to high-water mark. At the cable site, 1,500 feet below the gage, the bed is rocky and the banks high. Control is at head of Schultz Rapids about 200 feet below cable and 1,700 feet below gage.

Extremes of discharge.—Maximum stage recorded during year, 4.02 feet April 21, and 23 (discharge, 1,400 second-feet), minimum discharge estimated 340 second-feet February 9.

1914–1917: Maximum stage recorded, 9.0 feet, April 22 and 23, 1916 (discharge, 5,430 second-feet); minimum discharge, February 9, 1917.

Regulation.—Storage reservoirs are maintained by the Chippewa & Flambeau Improvement Co. on the headwaters of the Flambeau River. Of these reservoirs, Rest Lake, in sec. 9, T. 42 N., R. 5 E., with an allowable capacity of approximately 1.5 billion cubic feet, is the largest.

Accuracy.—Stage-discharge relation permanent except as affected by ice. Rating curve well defined between 356 and 3,480 second-feet. Gage read to quarter-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating curve except for periods in which stage-discharge relation was affected by ice, for which it was obtained by applying to rating table daily gage height corrected for ice effect by means of discharge measurements, observer's notes, and weather records. Gage not read on most Sundays part of April to July; discharge interpolated. Open-water records good; winter records fair.

Discharge measurements of Flambeau River near Butternut, Wis., during the year ending Sept. 30, 1917.

[Made by R. B. Kilgore.]

FLAMBEAU RIVER NEAR LADYSMITH, WIS.

LOCATION.—In SE. ¼ sec. 20, T. 35 N., R. 5 W., at H. J. Cornelissen's farm, about 6 miles by road northeast of Ladysmith, Rusk County, 21 miles below mouth of South Fork of Flambeau River, coming in from the left, and 28 miles above mouth of river.

DRAINAGE AREA.—1,940 square miles (measured on map issued by Wisconsin Geological & Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

RECORDS AVAILABLE.—January 2, 1914, to September 30, 1917. From February 15, 1905, to December 2, 1906, records were collected at a station in the city of Ladysmith, three-fourths of a mile south of the Minneapolis, St. Paul & Sault Ste. Marie Railway station, half a mile below the dam of the Menasha Pulp Co., and about 6 miles below the present station.

GAGE.—Chain, fastened to a cantilever arm supported by two trees on the left bank of the river, on the farm of H. J. Cornelissen; read by H. J. Cornelissen.

DISCHARGE MEASUREMENTS.—Made from cable 200 feet below gage.

CHANNEL AND CONTROL.—Bed composed of gravel and sand; free from vegetation and fairly permanent. At the gage section, channel is divided by a small sandy island; at the cable section the river flows in one channel; banks are medium high, wooded, and not subject to overflow. Control not well defined, formed by the channel below the gage.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year when chanel was clear of ice and logs 6.6 feet June 7, 8 (discharge 7,880 second-feet); minimum discharge, 605 second-feet March 10–17.

1903–1906 and 1914–1917: Maximum discharge recorded, 17,400 second-feet April 23, 1916; minimum discharge, 390 second-feet December 4, 1904.

ICE.—Large quantities of frazil ice form on the falls and rapids above the station and fill the channel for a distance of several miles from the gage to pond of the paper company's dam at Ladysmith, seriously affecting the stage-discharge relation.

REGULATION.—The Chippewa & Flambeau Improvement Co. operates storage reservoirs on Rest Lake and smaller reservoirs on Manitowish and Turtle rivers and Bear Creek. Weekly fluctuations at the gage are caused by operation of power plants at Park Falls and storage reservoirs; no daily fluctuation has been observed.

ACCURACY.—Stage-discharge relation permanent except as affected by logs and ice. Rating curve well defined between 770 and 17,000 second-feet, roughly approximate above and below these limits. Gage read once daily to quarter tenths. Daily discharge ascertained by applying daily gage height to rating table, except for periods in which stage-discharge relation was affected by ice or logs for which discharge was obtained by applying to rating table mean daily gage heights corrected for backwater by means of discharge measurements, observers' notes and weather records. Open-water records excellent except those for April, May, and June, when logs were in river, for which they are fair; winter records fair.

Discharge measurements of Flambeau River near Ladysmith, Wis., during the year ending Sept. 30, 1917.

JUMP RIVER AT SHELDON, WIS.

LOCATION.—In sec. 26, T. 33, N., R. 5 W., at highway bridge in Sheldon, Rusk County, 11 miles above confluence of Jump and Chippewa rivers.

DRAINAGE AREA.—510 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

RECORDS AVAILABLE.—July 22, 1915, to September 30, 1917.

GAGE.—Chain gage bolted to downstream handrail of bridge.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge.

CHANNEL AND CONTROL.—Heavy gravel, clean, and free from vegetation. Right bank high and not subject to overflow; left bank may be overflowed occasionally.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 6.89 feet at 8 a. m. April 22 (discharge, 4,020 second-feet); minimum discharge estimated 20 second-feet, January and February.

1915–1917: Maximum discharge 8,600 second-feet April 22, 1916; minimum discharge about 18 second-feet January 20, 1916.

ACCURACY.—Stage-discharge relation permanent except as affected by ice. Rating curve well defined between 45 and 5,930 second-feet. Gage read to quarter tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table except for period in which stage-discharge relation was affected by ice, for which it was obtained by applying to rating table mean daily gage height corrected for ice effect by means of discharge measurements, observer's notes, and weather records. Open-water records good; winter records fair.

Discharge measurements of Jump River at Sheldon, Wis., during the year ending Sept. 30, 1917.

[Made by R. B. Kilgore.]

EAU CLAIRE RIVER NEAR AUGUSTA, WIS.

LOCATION.—In sec. 12, T. 26 N., R. 6 E., at Trouble Water Bridge, about 7 miles northeast of Augusta, Eau Claire County. South Fork of Eau Claire River enters from left about 4 miles above station.

DRAINAGE AREA.—500 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

RECORDS AVAILABLE.—July 16, 1914, to September 30, 1917.

GAGE.—Chain gage on downstream side of bridge; read by Albert Wagner.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge or by wading at control about 500 feet downstream from bridge.

CHANNEL AND CONTROL.—Bed at bridge and above is sandy and very shifting; a short distance below the gage the channel narrows and a rock outcrop overlain with large boulders forms the control. Banks are high and not subject to overflow.

EXTREMES OF DISCHARGE.—Maximum open-water stage recorded, during year, 7.08 feet April 3 and 4 (discharge, 3,710 second-feet); a stage of 11.0 feet March 31 was due to backwater from ice; minimum discharge estimated at 25 second-feet January 3–5 and 21–25.

1914–1917: Maximum open-water stage recorded, 10.6 feet at noon April 1, 1916 (discharge, 7,180 second-feet); discharge less at stage of 11.0 feet March 31, 1917, which was due to backwater from ice; minimum discharge January, 1917.

ACCURACY.—Stage-discharge relation practically permanent except as affected by ice. Rating curve used October 1 to September 30, well defined from 87 to 5,520 second-feet; poorly defined outside these limits. Gage read to quarter tenths once a day. Daily discharge ascertained by applying daily gage height to rating table, except for period in which stage-discharge relation was affected by ice, for which it was obtained by applying to rating table mean daily gage height corrected for effect of ice by means of discharge measurements, observer's notes, and weather records. Open-water records good, except for low stages for which they are fair; winter records fair.

Discharge measurements of Eau Claire River near Augusta, Wis., during the year ending Sept. 30, 1917.

RED CEDAR RIVER NEAR COLFAX, WIS.

LOCATION.—In sec. 27, T. 30 N., R. 11 W., at highway bridge about 4½ miles north of Colfax, Dunn County. Hay River enters from right about 11 miles below, and Trout Creek, also from right, 3½ miles above station.

DRAINAGE AREA.—1,100 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

RECORDS AVAILABLE.—March 10, 1914, to September 30, 1917.

GAGE.—Chain gage attached to downstream side of bridge; read by Andrew Lundeguam.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge to which gage is attached.

CHANNEL AND CONTROL.—Bed composed of rock and gravel; small amount of grass growth during summer months; left bank high and not subject to overflow; right bank medium high and may be overflowed during extremely high water; control not well defined.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 4.94 feet at 10 a. m. April 3 (discharge 4,380 second-feet); minimum discharge recorded, 435 second-feet March 12.

1914–1917: Maximum stage recorded, 6.8 feet at 1 p. m., March 31, 1916 (discharge 6,990 second-feet); minimum stage recorded 0.80 foot November 19, 1914 (discharge about 385 second-feet), apparently caused by temporary holding back of the water by ice.

REGULATION.[1]—The following dams and reservoirs are used to regulate the flow in the Red Cedar River. Owing to operation of these reservoirs the flow at the station is not natural.

Reservoirs used to regulate flow of Red Cedar River.

Dam.	Location.	Approximate capacity (millions of cubic feet).
Long Lake	Sec. 24, T. 37 N., R. 11 W	1,000
Cedar Lake	Sec. 21, T. 36 N., R. 10 W	965
Birch Lake	Sec. 25, T. 37 N., R. 10 W	1,174
Bear Lake	Sec. 7, T. 36 N., R. 11 W	280
Chetek Lake	Sec. 20, T. 33 N., R. 10 W	998
		4,417

ACCURACY.—Stage-discharge relation nearly permanent, except as affected by ice and possibly by grass from June to September. One curve, well defined between 653 and 4,450 second-feet, was used during the year; curve extended and roughly approximate outside these limits. Gage read to quarter tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table except for period in which stage-discharge relation was affected by ice, for which it was ascertained by applying to rating table mean daily gage height corrected for effect of ice by means of discharge measurements, observer's notes and weather records. Open-water records good; winter records fair.

RED CEDAR RIVER AT CEDAR FALLS, WIS.

Location.—In sec. 6, T. 28 N., R. 12 W., at highway bridge near Cedar Falls, Dunn County, 4½ miles above crossing of Chicago, St. Paul, Minneapolis & Omaha Railway.

Drainage area.—Not measured.

Records available.—April 1, 1909, to September 30, 1917.

Gage.—Staff fastened to bridge pier; read by John G. Wood.

Discharge measurements.—No discharge measurements made at this station, which is maintained to determine fluctuation in stage.

Channel and control.—Channel rough and rocky, straight, and free from vegetation; banks high and not subject to overflow.

Extremes of stage.—Maximum stage recorded during year, 5.9 feet April 3 and 4; minimum stage, 0.0 foot, 5 p. m. March 11.

1909–1917: Maximum stage recorded, 6.1 feet April 1–3, 1916; minimum stage recorded 0.0 foot at 5 p. m. March 11, 1917. Minimum stages are caused by closing gates and wheels in dam above station.

Regulation.—The operation of storage reservoirs in the headwaters of the river (see "Regulation" in station description for Red Cedar River at Colfax, Wis.), together with storage at the power plant above the gaging station, modify the flow.

Accuracy.—Gage read twice daily to half-tenths. No measurements have been made, but stage-discharge relation believed permanent. Considerable diurnal fluctuation is observed, so that mean daily gage height does not represent the average stage.

Cooperation.—Gage-height record furnished by Wisconsin & Minnesota Light & Power Co.

Daily gage height, in feet, of Red Cedar River at Cedar Falls, Wis., for the year ending Sept. 30, 1917.

RED CEDAR RIVER AT MENOMONIE, WIS.

LOCATION.—In sec. 21, T. 28 N., R. 13 W., about 900 feet below power house of Wisconsin & Minnesota Light & Power Co., Menominie, Dunn County, 13 miles above the confluence of Red Cedar and Chippewa rivers. Wilson Creek discharges from right into service reservoir just above station.

DRAINAGE AREA.—1,810 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

RECORDS AVAILABLE.—June 16, 1907, to September 5, 1908; May 9, 1913, to September 30, 1917.

GAGE.—Barrett & Lawrence water-stage recorder installed May 9, 1913, over a wooden well on right bank of river about 1 mile above the site of old gage attached to a highway bridge about 200 rods west of the Chicago & North Western Railway station west of Menomonie, which was read from June 16, 1907, to September 5, 1908. No relation between datums of the two gages. Gage inspected by E. Kasrud.

DISCHARGE MEASUREMENTS.—Made from highway bridge about 1 mile below the gage.

CHANNEL AND CONTROL.—Bed at gage composed of heavy gravel; left bank high and not subject to overflow; right bank of medium height will be overflowed at flood stages; bed at measuring section sandy and liable to shift; both banks high at measuring section and not subject to overflow.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year about 6.3 feet April 3 (discharge, 8,300 second-feet); minimum stage recorded 1.92 feet at 1 p. m. November 20 (discharge, 394 second-feet).

1907–8 and 1913–1917: Maximum discharge, 12,700 second-feet March 31 and April 1, 1916; minimum discharge, 100 second-feet November 9, 1907.

REGULATION.—Considerable diurnal fluctuation in stage at the gage section is caused by the operation of the power plants of the Wisconsin & Minnesota Light & Power Co. at Menomonie and Cedar Falls. (See "Regulation" in station description for Red Cedar River at Colfax, Wis.)

ICE.—Stage-discharge relation not affected by ice.

ACCURACY.—Stage-discharge relation changed during high water of April 1916, but has been fairly permanent since. Ice does not affect the stage-discharge relation at this station owing to relatively warm water coming from service reservoir. Rating curve well defined between 610 and 1,910 second-feet, and between 3,910 and 9,220 second-feet. Curve extended outside these limits and roughly approximate only. Operation of water-stage recorder satisfactory except for brief periods. Daily-discharge record October 1 to September 30 except for brief periods obtained with discharge integrator. Records good except for periods when gage was not in operation, for which they are only roughly approximate.

Discharge measurements of Red Cedar River at Menomonie, Wis., during the year ending Sept. 30, 1917.

[Made by R. B. Kilgore.]

ZUMBRO RIVER AT ZUMBRO FALLS, MINN.

LOCATION.—Near east border of sec. 31, T. 110 N., R. 14 W., at highway bridge at Zumbro Falls, about 1,500 feet below mouth of Spring Creek, 6½ miles below mouth of South Branch.

DRAINAGE AREA.—1,120 square miles.

RECORDS AVAILABLE.—June 8, 1909, to September 30, 1917, when station was discontinued.

GAGE.—Chain attached to the upstream handrail of bridge near left end; read by A. H. Sugg.

DISCHARGE MEASUREMENTS.—Made from the bridge or by wading.

CHANNEL AND CONTROL.—Bed of stream is fine sand; shifts considerably; a slight riffle a few hundred feet below gage acts as a partial control during low stages; right bank is fairly low and is overflowed during high flood stages; left bank not subject to overflow.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year 19.04 feet at 4.50 p. m. March 25 (discharge, about 14,800 second-feet); flood peak was increased somewhat by going out of dam at Mazeppa, about 6 miles upstream, during the afternoon of March 25. Dam created a head of 22 feet and had a pond area of about 150 acres. Minimum discharge estimated 150 second-feet January 13 to February 15.

1907–1917: Maximum stage recorded March 25, 1917; minimum open-water stage recorded, 4.50 feet at 8 a. m. January 10 and 21, 1914 (discharge, about 128 second-feet); 106 second-feet was measured by current meter January 27, 1915.

High-water of June, 1908, which reached a stage of 26.7 feet above datum of present gage, is marked by a spike in a telephone post near the railroad station at Zumbro Falls; high water of April, 1888, reached a stage of approximately 29.7 feet, as shown by a mark not so well defined as that of the flood of 1908.

ICE.—Stage-discharge relation not seriously affected by ice except during and after extremely cold weather, when ice forms below the gage and causes backwater for short periods. A short distance above the gage the river receives about 8 second feet of spring water from Spring Creek, which is warm enough to keep it free from ice for a considerable distance during most winter weather.

REGULATION.—The slight artificial regulation at the power plants above Zumbro Falls is not observable at the gage.

ACCURACY.—Stage-discharge relation not permanent; change occurred during high-water of March. Rating curve used October 1 to March 22 and May 29 to September 30, poorly defined; curve used March 23 to May 28 poorly defined throughout. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table except during period when stage-discharge relation was affected by ice, for which it was obtained by applying to rating table mean daily gage height corrected for effect of ice by means of discharge measurement, observer's notes, and weather records. Open-water records good except those for flood stages, which are subject to error; winter records fair.

Discharge measurements of Zumbro River at Zumbro Falls, Minn., during the period Oct. 1, 1916, to Oct. 6, 1917.

SOUTH BRANCH OF ZUMBRO RIVER NEAR ZUMBRO FALLS, MINN.

LOCATION.—In sec. 22, T. 109 N., R. 14 W., at Woodville Bridge, 1¼ miles above mouth of river, 6 miles below mouth of Middle Branch, and 6 miles southwest of Zumbro Falls, Wabasha County.

DRAINAGE AREA.—821 square miles.

RECORDS AVAILABLE.—June 16, 1911, to September 30, 1917, when station was discontinued.

GAGE.—Chain gage attached to the downstream handrail of bridge near center of river; read by W. M. Whipple.

DISCHARGE MEASUREMENTS.—At high and medium stages made from downstream side of the bridge; at low stages made by wading.

CHANNEL AND CONTROL.—Bed of stream consists chiefly of sand and gravel. Control consists of cobble stones and rock at a well-defined riffle a short distance below the gage; fairly permanent.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 14.1 feet at 6 p. m. March 23 (discharge, about 12,100 second-feet); minimum discharge estimated, 100 second-feet February 11–24.

1911–1917: Maximum stage recorded March 23, 1917; minimum stage recorded, 1.80 feet December 26, 1914 (discharge, 62 second-feet).

ICE.—Stage-discharge relation seriously affected by ice; flow estimated from discharge measurements, observer's notes, and weather records.

REGULATION.—Effects of operation of small power plants above the station not noticeable at gage.

ACCURACY.—Stage-discharge relation fairly permanent except as affected by ice. Rating curve fairly well defined. Gage read to quarter-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table except during period when stage-discharge relation was affected by ice, for which it was ascertained by applying to rating table mean daily gage height corrected for effect of ice, by means of discharge measurements, observer's notes, and weather records. Open-water records good except those for extreme flood stages, which are subject to error; winter records fair.

Discharge measurements of South Branch of Zumbro River near Zumbro Falls, Minn., during the period Oct. 1, 1916, to Oct. 6, 1917.

TREMPEALEAU RIVER AT DODGE, WIS.

LOCATION.—In sec. 11, T. 19 N., R. 10 W., at highway bridge in Dodge, Trempealeau County, 9 miles above mouth of river.

DRAINAGE AREA.—633 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

RECORDS AVAILABLE.—December 13, 1913, to September 30, 1917.

GAGE.—Chain gage attached to downstream side of bridge; read by J. Johnson and F. E. Shappee.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge or by wading.

CHANNEL AND CONTROL.—Sand; likely to shift. Banks of medium height and may be overflowed during extreme floods.

EXTREMES OF DISCHARGE.—Maximum discharge 1,640 second-feet, March 30 and 31; minimum discharge about 120 second-feet, January 21–23.

1914–1917: Maximum stage recorded, 8.35 feet, June 9, 1914 (discharge, 3,340 second-feet); minimum discharge, January 21–23, 1917.

ICE.—Stage-discharge relation seriously affected by ice.

REGULATION.—No power plants above station have sufficient capacity to affect the natural flow of the river.

ACCURACY.—Stage-discharge relation not permanent. Two rating curves used as follows: October 1 to March 31, fairly well defined between 196 and 1,800 second-feet; April 1 to September 30, well defined between 191 and 1,800 second-feet, and fairly well defined between 1,800 and 3,080 second-feet. Gage read to quarter-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table, except for period when stage-discharge relation was affected by ice, for which it was obtained by applying to rating table mean daily gage height corrected for effect of ice by means of discharge measurements, observer's notes, and weather records. Open-water records good, except at extreme flood stages, for which they are fair; winter records fair.

Discharge measurements of Trempealeau River at Dodge, Wis., during the year ending Sept. 30, 1917.

BLACK RIVER AT NEILLSVILLE, WIS.

Location.—In sec. 15, T. 24 N., R. 2 W., at lower highway bridge in Neillsville, Clark County. O'Neil Creek enters from left about a mile above gage and Cunningham Creek, also from left, about 1½ miles below.

Drainage area.—774 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

Records available.—April 7, 1905, to March 31, 1909; December 11, 1913, to September 30, 1917.

Gage.—Chain gage fastened to downstream side of highway bridge; read by A. Bissell.

Discharge measurements.—Made from downstream side of bridge or by wading in vicinity of bridge.

Channel and control.—Bed composed of heavy gravel and rock; control at head of rapids, a few hundred feet below gage; banks high and rocky; water will not overflow the banks at the gage section.

Extremes of discharge.—Maximum stage recorded during year, 10.35 feet at 8 a. m. April 4 (discharge, 7,200 second-feet); minimum discharge estimated, 25 second-feet December 25–31. Owing to diurnal fluctuations at such low stages it is likely that the absolute minimum was somewhat less.

1905–1909 and 1913–1917: Maximum stage recorded, 19.8 feet June 6, 1905 (discharge, about 29,400 second-feet). It is probable that the maximum discharge which occurred October 6, 1911, exceeded 29,000 second-feet, although data are not available regarding the stage at the gage section during this flood. Minimum stage recorded during open-water periods, 2.4 feet October 9, 1905 (discharge, about 20 second-feet).

Regulation.—Several dams on Black River and tributaries upstream from Neillsville are used to create a head for developing power. The operation of these plants causes a diurnal fluctuation at the gage, especially during the winter, when the flow is at a minimum.

Accuracy.—Stage-discharge relation practically permanent except as affected by ice. Rating curve well defined from 48 to 14,300 second-feet; fairly well defined below 48 second-feet and extended above 14,300 second-feet. Gage read to quarter-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table except for periods in which stage-discharge relation was affected by ice, for which it was obtained by applying to rating table gage height corrected for effect of ice by means of discharge measurements, observer's notes, and weather records. Open-water records good, except for extremely low stages, for which they are fair; winter records poor.

Discharge measurements of Black River at Neillsville, Wis., during the year ending Sept. 30, 1917.

LA CROSSE RIVER NEAR WEST SALEM, WIS.

LOCATION.—In sec. 32, T. 17 N., R. 6 W., La Crosse County, at Highway bridge 2 miles west of West Salem and 10 miles above mouth of river. Dutch Creek enters from right 6 miles above station.

DRAINAGE AREA.—412 square miles (measured on map issued by Wisconsin Geological & Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

RECORDS AVAILABLE.—December 22, 1913, to September 30, 1917.

DISCHARGE MEASUREMENTS.—Made from upstream side of bridge at medium and high stages; at low stages made by wading.

CHANNEL AND CONTROL.—Bed heavy gravel and rock. Right bank high and not subject to overflow; left bank above the gage low, and subject to overflow at flood stages. Channel free from vegetation; control for low stages a rocky riffle with a fall of about 6 inches. Control is apparently drowned out at a stage of about 2.2 feet on the gage as shown by a reversal in the rating curve.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 7.4 feet, at 5 p. m. March 24 (discharge, about 2,850 second-feet); minimum discharge, 130 second-feet, January 14.

1913–1917: Maximum stage recorded March 24, 1917; minimum discharge, 130 second-feet, November 17, 1914, and January 14, 1917.

ICE.—Stage-discharge relation seriously affected by ice.

REGULATION.—Diurnal fluctuation at low stages amounting to 0.10 to 0.40 foot, is caused by the operation of power plants, especially the Neshonock dam a few miles above station.

ACCURACY.—Stage-discharge relation permanent, except as affected by ice. Rating curve well defined between 212 and 2,300 second-feet. Gage read to quarter tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table except for periods in which stage-discharge relation was affected by ice, for which it was obtained by applying to rating table mean daily gage height corrected for effect of ice by means of discharge measurements, observer's notes, and weather records. Open-water records good, except for low stages, for which they are fair; winter records fair.

Discharge measurements of La Crosse River near West Salem, Wis., during the year ending Sept. 30, 1917.

ROOT RIVER NEAR HOUSTON, MINN.

Location.—In sec. 34, T. 104 N., R. 6 W., at highway bridge 1 mile east of Houston, Houston County, 1 mile above mouth of South Root River.

Drainage area.—1,560 square miles.

Records available.—May 28, 1909, to Sept. 30, 1917, when station was discontinued.

Gage.—Vertical staff bolted to the downstream side of the stone abutment, right end of bridge, read by Olaf Larson. Prior to June 28, 1913, gage was attached to piling just above the right abutment. The datum of the present gage was changed slightly on date of installation to allow for slight slope in river between the two points.

Discharge measurements.—Made from the downstream side of bridge.

Channel and control.—No well-defined control. Bed of stream is silt and fine sand that scours during floods and gradually fills in afterwards. Banks subject to overflow at stage of about 8.5 feet, the overflow at the gage attaining at times a width of about 5,000 feet. Floods on the South Root, which enters the main Root about a mile below station, at times produce considerable backwater at the gage.

Extremes of discharge.—Maximum stage recorded during year, about 11.95 feet March 24 (discharge estimated, because of ice, about 17,000 second-feet); minimum discharge estimated during period river was frozen over was 280 second-feet Feb. 12 to 22, 24 and March 4.

1909–1917: Maximum stage recorded March 24, 1917; minimum stage recorded during open water period, 0.80 foot July 17, 1911 (discharge 267 second-feet); a discharge of 231 second-feet was measured by current meter on January 23, 1914.

Ice.—Stage-discharge relation seriously affected by ice.

Regulation.—Nearest dam above station is at Rushford. As the flow is ample at all times for the power generated at that point, it is not held back during certain parts of the day, and the dam has no influence on the flow at Houston.

Accuracy.—Stage-discharge relation not permanent; change occurred in control section between June and September. Rating curve used October 1 to June 30 well defined between 500 and 10,500 second-feet. Daily discharge July 1 to Sept. 30 determined by shifting-control method. Daily discharges during remainder of period obtained by applying mean daily gage height to rating table except during period when stage-discharge relation was affected by ice, for which it was ascertained by applying to rating table mean daily gage height corrected for effect of ice by means of discharge measurements, observer's notes, and weather records. Records fair except those for winter, which are subject to error.

Discharge measurements of Root River near Houston, Minn., during the year ending Sept. 30, 1917.

NORTH BRANCH OF ROOT RIVER NEAR LANESBORO, MINN.

LOCATION.—In sec. 6, T. 103 N., R. 9 W., at first highway bridge 1 mile above junction of North and South branches, 3 miles north of Lanesboro, Fillmore County, and about 5 miles below mouth of a small creek that enters from the west.

DRAINAGE AREA.—647 square miles.

RECORDS AVAILABLE.—March 9, 1910, to September 30, 1914; and July 16, 1915, to September 30, 1917, when station was discontinued.

GAGE.—Chain gage on floor of bridge, downstream side, near right bank; read by Olaf Waage.

DISCHARGE MEASUREMENTS.—Made from the downstream side of the bridge, from the railroad bridge just above the junction with the South branch (at flood stages) or by wading just above the gage.

CHANNEL AND CONTROL.—Bed composed of sand and light gravel. A few hundred feet below the gage the channel is narrowed by a low island and there is a slight riffle that constitutes a control at low stages and is practically permanent. As there is more than 10 feet fall between the station and the mouth of the South Branch backwater from that stream is improbable. At a stage of 6 feet the river overflows into a former channel 1,000 feet back from the right bank. At extreme flood stages the right bank is overflowed to a width of a quarter of a mile.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 13.0 feet March 23 (discharge estimated, because of ice, about 12,000 second-feet); minimum discharge, during period river was frozen over, February 25–28, estimated at 90 second-feet.

1910–1917: Maximum stage recorded March 23, 1917; minimum open-water stage recorded, 1.71 feet July 4, 1911 (discharge, 38 second-feet).

ICE.—Stage-discharge relation seriously affected by ice.

REGULATION.—Several miles above the station is a power plant that is run under a varying load for light and power, but inspection of the morning and evening gage heights indicates that the diurnal fluctuation at the gage is slight.

ACCURACY.—Stage-discharge relation changed during high water of March. Rating curve used before change well defined between 186 and 1,350 second-feet; curve used after change fairly well defined between 155 and 3,400 second-feet. Gage read to quarter tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table except for periods in which the stage-discharge relation was affected by backwater from ice for which it was ascertained by applying to the rating table mean daily gage height corrected for effect of ice by means of discharge measurements, observer's notes, and weather records. Records fair except those for winter, which are subject to error.

Discharge measurements of North Branch Root River near Lanesboro, Minn., during the year ending Sept. 30, 1917.

WISCONSIN RIVER AT WHIRLPOOL RAPIDS, NEAR RHINELANDER, WIS.

LOCATION.—In sec. 4, T. 35 N., R. 8 E., Lincoln County, at head of Whirlpool Rapids, 1 mile below mouth of outlet of Crescent Lake (coming in from right), and about 3 miles downstream from power station of Rhinelander Power Co., 10 miles southwest of Rhinelander.

DRAINAGE AREA.—1,160 square miles (measured on map issued by Wisconsin Geological & Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

RECORDS AVAILABLE.—September 15, 1915, to September 30, 1917; December 1, 1905, to September 30, 1915, for station, about 3 miles upstream.

GAGE.—Stevens continuous water-stage recorder, on right bank, in wooden shelter, well and intake.

DISCHARGE MEASUREMENTS.—Made from a cable 150 feet upstream from gage.

CHANNEL AND CONTROL.—Bed of stream heavy gravel and rock. Banks medium high and not subject to overflow. Control is head of rapids, 100 feet downstream from gage; well defined and permanent.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year 4.15 feet at 10 a. m. April 25 (discharge, 2,900 second-feet); minimum stage recorded 0.86 foot at 8.30 p. m. August 19 (discharge, 232 second-feet).

1905–1917: Maximum stage recorded 5.61 at 10:00 p. m. April 22, 1916 (discharge 5,250 second-feet); minimum discharge recorded, at old station, zero during August and September, 1907, and June, 1908. Minimum flow caused almost entirely by regulation, and at the present station will never be zero discharge. Minimum discharge at new location, 1915–1917, 0.85 foot 5 p. m. August 20, 1916 (discharge 228 second-feet).

REGULATION.—Above the station are 14 reservoirs [1] which are operated by the Wisconsin Valley Improvement Co., for the purpose of regulating the flow in Wisconsin River. The aggregate capacity of these reservoirs is 2.8 billion cubic feet during the summer, and 3.6 billion cubic feet during the winter. Owing to the operation of these various storage reservoirs and the service reservoirs of three powerplants on river above this station, the flow at the station is not natural.

ACCURACY.—Stage-discharge relation permanent except as affected by ice. Rating curve well defined between 212 and 5,410 second-feet. Recording gage not in operation October 17 to November 1, December 25 to March 9, and March 21–25. Daily discharge obtained by use of discharge integrator except for periods during which stage-discharge relation was affected by ice or gage was not in operation, for which it was obtained from discharge measurements, recording gage graph and observer's notes, and weather records and comparison of flow of Tomahawk River near Bradley and Wisconsin River at Merrill. Open-water records excellent, except those for periods when gage was not in operation, which may be considerably in error; winter records possibly poor.

Discharge measurements of Wisconsin River at Whirlpool Rapids, near Rhinelander, Wis., during the year ending Sept. 30, 1917.

[Made by R. B. Kilgore.]

WISCONSIN RIVER NEAR NEKOOSA, WIS.

LOCATION.—In sec. 15, T. 21 N., R. 5 E., 1½ miles below Nekoosa, Wood County. Tenmile Creek enters from left about 4 miles below station, and Big Roche a Cri Creek, also from left, about 38 miles below.

DRAINAGE AREA.—5,500 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

RECORDS AVAILABLE.—May 21, 1914, to September 30, 1917.

GAGE.—Stevens water-stage recorder installed July 18, 1916, in wooden shelter on right bank; prior to that date Gurley water-stage recorder at same location. Gage attended by Henry Mans.

DISCHARGE MEASUREMENTS.—Made from cable a short distance upstream from gage.

CHANNEL AND CONTROL.—Gravel; clean; practically permanent. Banks are high and are rarely overflowed.

EXTREMES OF DISCHARGE.—Maximum stage during year, 10.02 feet at 10 p. m. April 5 (discharge, 24,700 second-feet); minimum discharge, 835 second-feet January 10.

1914–1917: Maximum stage, as determined by levels run to high-water marks after water had receded, about 15.3 feet during the flood of June 6 to 9, 1914 (discharge, 54,600 second-feet); minimum stage recorded, 0.45 foot at 11 a. m. October 7, 1915 (discharge, 595 second-feet). Minimum flow is due to regulation.

ICE.—Stage-discharge relation seriously affected by ice.

REGULATION.—No storage reservoirs discharging into Wisconsin River between Nekoosa and Merrill. See "Regulation" in station description of Wisconsin River at Merrill (p. 111). Between Nekoosa and Merrill are 12 dams operated for power.

ACCURACY.—Stage-discharge relation practically permanent, except as affected by ice. Rating curve well defined between 1,160 and 52,100 second-feet. Operation of water-stage recorder satisfactory, except October 1 and November 22. Daily discharge ascertained by use of discharge integrator, except December 15 to March 29, for which it was obtained by applying to rating table, mean daily gage height corrected for effect of ice by means of discharge measurements, recording gage records, observer's notes, and weather records. Open-water records excellent; winter records fair.

Discharge measurements of Wisconsin River near Nekoosa, Wis., during the year ending Sept. 30, 1917.

WISCONSIN RIVER AT MUSCODA, WIS.

LOCATION.—In sec. 1, T. 8 N., R. 1 W., at highway bridge 1 mile north of Muscoda, Grant County. Eagle Mill Creek enters from right about half a mile below station, and Underwood Creek from left about 4½ miles above.

DRAINAGE AREA.—10,300 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

RECORDS AVAILABLE.—December 21, 1902, to December 31, 1903; December 4, 1913, to September 30, 1917. Gage heights November 1, 1908, to December 31, 1912, published in United States Weather Bureau bulletin, Daily River Stages, parts 9, 10, and 11.

GAGE.—Chain gage fastened to hand railing on upstream side of bridge; read by William Hessler. Elevation of zero of present gage about 12.62 feet above that of gage maintained December 20, 1902, to December 3, 1913, elevation of gage during period November, 1908, to December 3, 1913, as read and published by United States Weather Bureau was about the same as that of present gage, sea-level elevation of which is 666.2 feet.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year 6.95 feet April 11 (discharge 32,800 second-feet); minimum discharge estimated 3,400 second-feet February 12.

1903 and 1914–1917: Maximum stage recorded, 22.70 feet September 23, 1903, corresponding to 10.1 feet for present gage datum (discharge, about 60,500 second-feet); minimum stage recorded 0.7 foot December 2, 1914, and 5 p. m. July 24, 1915 (discharge about 3,140 second-feet).

According to the records of the United States Weather Bureau[1] (see note under "Gage") on June 11, 1881, the river reached a stage of 11.1 feet and during August, 1868, zero on gage; discharge not computed owing to possible changes in channel and datum of gage.

REGULATION.—Nearest power plant above station is at Prairie du Sac, about 40 miles distant; since the last part of 1915 considerable diurnal fluctuation has been observed at the gage. Owing to regulation by storage in the headwaters the flow at this station is not natural.

ACCURACY.—Stage-discharge relation not permanent; affected by ice. Rating curve used during 1917, fairly well defined between 5,200 and 45,000 second-feet. Gage read to quarter-tenths twice a day. Daily discharge ascertained by applying mean daily gage height to rating table, except for periods when stage-discharge relation was affected by ice, for which it was obtained by applying to rating table mean daily gage height corrected for effect of ice by means of discharge measurements, observer's notes, and weather records. Open-water records good, except for extreme high and low stages, for which they are fair; winter records roughly approximate.

TOMAHAWK RIVER NEAR BRADLEY, WIS.

LOCATION.—In sec. 16, T. 36 N., R. 6 E., 2 miles west of Cassion, 4 miles north of Bradley, Oneida County, 4 miles downstream from mouth of Bearskin Creek (coming in from right), and 8 miles above mouth of river.

DRAINAGE AREA.—422 square miles.

RECORDS AVAILABLE.—September 18, 1914, to September 30, 1917.

GAGE.—Chain gage fastened to cantilever arm on the right bank; read by Frank Sutherland.

DISCHARGE MEASUREMENTS.—Made from cable half a mile below gage.

CHANNEL AND CONTROL.—Bed at gage and a short distance below, sandy and likely to shift. Control is formed by rapids about 2,000 feet below gage. Bed at cable section heavy gravel; permanent. When a head of 15 feet is maintained in Rice Lake storage dam, in sections 4 and 9, T. 35 N., R. 6 E., backwater will extend halfway up the rapids which are below the gage, and may affect the discharge relation. The maximum head maintained during year at the reservoir was 13 feet 1 inch, during July 21, which apparently did not affect the control for the gage.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year 4.31 feet at 7.25 a. m. April 22 (discharge, 927 second-feet); minimum stage, 1.72 feet at 6.45 a. m. September 12 (discharge, 229 second-feet).

1914–1917: Maximum stage recorded, 6.88 feet April 24, 1916 (discharge, 2,190 second-feet); minimum stage recorded, September 12, 1917.

ICE.—Stage-discharge relation seriously affected by ice.

REGULATION.—The following reservoirs are maintained upstream from the station for the purpose of regulating the flow in the Wisconsin River.

Dams and reservoirs on Tomahawk River.

Name.	Location of reservoir.	Location of dam.	Area of reservoir.	Drainage area.	Capacity (millions of cubic feet).

Total.	....	....	14.31	98.67	443	803

ACCURACY.—Stage-discharge relation practically permanent except as affected by ice. Rating curve well defined between 240 and 1,970 second-feet. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table, except for periods in which stage-discharge relation was affected by ice, for which it was obtained by applying to rating table mean daily gage height corrected for effect of ice by means of discharge measurements, observer's notes, and weather records. Open-water records good except for extremely low stages for which they are fair; winter records fair.

Discharge measurements of Tomahawk River near Bradley, Wis., during the year ending Sept. 30, 1917.

PRAIRIE RIVER NEAR MERRILL, WIS.

LOCATION.—On line between secs. 20 and 29, T. 32 N., R. 7 E., at highway bridge 4½ miles northeast of Merrill, Lincoln County, and about 5½ miles above mouth of river. Haymeadow Creek enters from left about 5 miles above station.

DRAINAGE AREA.—164 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

RECORDS AVAILABLE.—January 18, 1914, to September 30, 1917.

GAGE.—Chain gage attached to upstream side of bridge; read by Mrs. Meta Krause.

DISCHARGE MEASUREMENTS.—At low stages made by wading; at medium and high stages from downstream side of bridge to which gage is attached.

Channel and control.—Bed composed of gravel; clean and free from vegetation. Left bank high, not subject to overflow; both banks wooded. Control not well defined.

Extremes of discharge.—Maximum stage recorded during year, 4.0 feet June 8 (discharge, 870 second-feet); minimum discharge about 80 second-feet January 11, 12, and 16.

1914–1917: Maximum stage recorded, 6.1 feet April 22, 1916 (discharge, 2,290 second-feet); minimum discharge, 72 second-feet, by discharge measurement January 4, 1915. Absolute minimum occurred during winter period 1914–15, and was probably somewhat less than 72 second-feet.

Ice.—Stage-discharge relation seriously affected by ice.

Regulation.—None.

Accuracy.—Stage-discharge relation permanent. Rating curve well defined between 103 and 2,200 second-feet. Gage read to half-tenths once a day. Daily discharge ascertained by applying daily gage height to rating table, except for periods in which stage-discharge relation was affected by ice, for which it was obtained by applying to rating table mean daily gage height corrected for effect of ice by means of discharge measurements, observer's notes, and weather records. Open-water records excellent; winter records good.

EAU CLAIRE RIVER AT KELLY, WIS.

LOCATION.—In sec. 13, T. 28 N., R. 8 E., at highway bridge three-quarters of a mile below Kelly, Marathon County, about a mile above mouth of Big Sandy Creek, which enters from right, and 4½ miles above mouth of river.

DRAINAGE AREA.—326 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

RECORDS AVAILABLE.—January 1, 1914, to September 30, 1917.

GAGE.—Chain gage fastened to downstream side of highway bridge; read by W. Woolsey.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge or by wading below bridge.

CHANNEL AND CONTROL.—Bed composed of heavy gravel and rock; gage is in the rapids which form the control. Banks medium high and not subject to overflow.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 3.22 feet at 10 a. m. April 4 (discharge, 1,310 second-feet); minimum discharge estimated 50 second-feet for several days in January.

1914–1917: Maximum stage recorded, 5.1 feet April 22 and 23, 1916 (discharge, 3,270 second-feet); mimimum open-water stage recorded, 0.45 foot, August 13, 14, 15, Oct. 2 and 3, 1914 (discharge, about 40 second-feet). Discharge January 14, 17, and 18, 1916, estimated at 40 second-feet; minimum for winter period probably somewhat below this figure.

ACCURACY.—Stage-discharge relation permanent, except as affected by ice. Rating curve well defined between 71 and 3,150 second-feet. Gage read to quarter tenths twice daily except Sundays. Daily discharge ascertained by applying mean daily gage height to rating table, except for periods in which stage-discharge relation was affected by ice, for which it was obtained by applying to rating table mean daily gage height corrected for effect of ice by means of discharge measurements, observer's notes, and weather records. Discharge for practically all Sundays interpolated. Open-water records good; winter records fair.

Discharge measurements of Eau Claire River at Kelly, Wis., during the year ending Sept. 30, 1917.

BIG EAU PLEINE RIVER NEAR STRATFORD, WIS.

LOCATION.—In sec. 13, T. 27 N., R. 3 E., at highway bridge at a place known locally as Weber Farm, about 2 miles north of Stratford, Marathon County, about 1 mile above Chicago & North Western Railway bridge. Dill Creek enters from right about 5 miles above station.

DRAINAGE AREA.—223 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

RECORDS AVAILABLE.—July 24, 1914, to September 30, 1917.

GAGE.—Sloping gage, reading from 1.0 to 15.6 feet, on right bank of the river, and vertical staff gage, reading from 15 to 18 feet, at upper end of sloping gage; read by Christian Weber.

DISCHARGE MEASUREMENTS.—Made by wading about 1,000 feet below gage or from the highway bridge.

CHANNEL AND CONTROL.—Bed composed of heavy gravel and rock; control at head of rapids 400 feet below gage. Both banks at gage are high and will be overflowed only at stage of about 15 feet and above.

EXTREMES OF DISCHARGE.—Maximum stage recorded during open-water period of year 7.42 feet at 6.30 a. m. April 4 (discharge, 3,670 second-feet); minimum open-water discharge, 11 second-feet December 22–30.

1914–1917: Maximum recorded stage 8.85 feet at 6 p. m. April 21, 1916 (discharge, 5,540 second-feet); minimum discharge, 3.0 second-feet, by current-meter measurement February 5, 1915. The flood of June, 1914, reached a maximum height of 20.7 feet as determined by levels run to high-water marks.

ACCURACY.—Stage-discharge relation practically permanent, except as affected by ice. Rating curve fairly well defined between 5 and 4,000 second-feet; gage read to quarter-tenths twice daily. Daily discharge obtained by applying mean daily gage height to rating table; estimated December 5–10, 31 and April 1–3 when stage-discharge relation was affected by ice. High-stage records good; records for medium and low stage fair.

Discharge measurements of Big Eau Pleine River near Stratford, Wis., during the year ending Sept. 30, 1917.

PLOVER RIVER NEAR STEVENS POINT, WIS.

LOCATION.—In sec. 1, T. 24 N., R. 8 E., Portage County, at Fast Waters highway bridge, 5 miles northeast of Stevens Point and 7 miles above mouth of river.

DRAINAGE AREA.—136 square miles.

RECORDS AVAILABLE.—January 5, 1914, to September 30, 1917.

GAGE.—Metal vertical staff gage bolted to left abutment, downstream side of bridge; read by C. A. Van Order.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge.

CHANNEL AND CONTROL.—Bed composed of heavy gravel and small rock; permanent and free from vegetation. At high stages both banks will be overflowed around the bridge. Control not well defined but is probably small rapids below gage.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 2.55 feet at 8 a. m. May 1 (discharge, 452 second-feet); minimum discharge estimated 45 second-feet, February 5–7.

1914–1917: Maximum stage recorded, 4.75 feet, June 5, 1914 (discharge, about 1,570 second-feet); minimum discharge estimated 45 second-feet, February 5–7, 1917.

ICE.—Stage-discharge relation seriously affected by ice.

REGULATION.—Two dams are used in connection with grist mills above the station, but the plants have little pondage so that the flow at the gage, except for brief periods, is nearly natural.

ACCURACY.—Stage-discharge relation probably permanent, except as affected by ice. Rating curve used October 1 to April 2 well defined between 116 and 1,370 second-feet; curve used April 3 to September 30 fairly well defined from 105 to 1,370 second-feet. Gage read to quarter tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table; except during periods when stage-discharge relation is affected by ice, for which it was ascertained by applying to rating table mean daily gage height corrected for effect of ice by results of discharge measurements, observer's notes, and weather records. Open-water records fair, except for extremely low stages, when diurnal fluctuation may cause some error; winter records roughly approximate.

Discharge measurements of Plover River near Stevens Point, Wis., during the year ending Sept. 30, 1917.

BARABOO RIVER NEAR BARABOO, WIS.

LOCATION.—In sec. 33, T. 12 N., R. 7 E., at highway bridge 4 miles downstream from Baraboo, Sauk County, about 3 miles below creek rising near Devils Lake, coming in from right, and 15 miles above mouth of river.

DRAINAGE AREA.—572 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

RECORDS AVAILABLE.—December 18, 1913, to September 30, 1917.

GAGE.—Chain gage, attached to upstream side of bridge; read by Miss Agnes Schneider.

DISCHARGE MEASUREMENTS.—Made from downstream side of highway bridge to which gage is attached.

CHANNEL AND CONTROL.—Bed composed of sand and mud; control not well defined. Water confined to one channel except at flood stages, when right bank is overflowed for a distance of 1,000 feet.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, about 17.5 feet March 26 (discharge, 4,200 second-feet); minimum discharge, 100 second-feet January 31.

1914–1917: Maximum stage recorded about 17.5 feet March 26, 1917 (discharge, 4,200 second-feet); minimum stage, 0.71 foot, at 7.30 a. m., July 26, 1916 (discharge, 76 second-feet).

ICE.—Stage-discharge relation seriously affected by ice.

REGULATION.—In the vicinity of Baraboo, 4 miles above the station, there are four dams, and one at Reedsburg, 18 miles above the station. Smaller plants are also operated on the tributaries. The operation of these various plants causes diurnal fluctuation at the gage of about 0.3 foot at low-water stages. Estimates of mean monthly discharge probably represent nearly the natural flow.

ACCURACY.—Stage-discharge relation changed during high water of March, 1917. Rating curve used October 1, 1915, to March 21, 1917, fairly well defined between 167 and 2,600 second-feet; extended and roughly approximate above and below these limits. Curve used March 22 to September 30, 1917, fairly well defined between 150 and 3,270 second-feet. Gage read to quarter tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table, except for periods when stage-discharge relation was affected by ice, for which it was ascertained by applying to rating table mean daily gage height corrected for effect of ice by means of discharge measurements, observer's notes, and weather records. Open-water records good; winter records roughly approximate.

Discharge measurements of Baraboo River, near Baraboo, Wis., during the year ending Sept. 30, 1917.

NOTE.—Stage-discharge relation affected by ice Dec. 13, 1916, to Mar. 10, 1917. Water above gage on Mar. 25 and 26, 1917; discharge based on stage as noted on bridge structure. Discharge record for the year ending Sept. 30, 1915, supersedes that published in Water-Supply Paper 405, p. 143, owing to a revision of rating curve above 500 second-feet.

Monthly discharge of Baraboo River near Baraboo, Wis., for the years ending Sept. 30, 1915 and 1917.

[Drainage area, 572 square miles.]

NOTE.—Monthly discharge record for the year ending Sept. 30, 1915, supersedes that published in Water-Supply Paper 405, p. 144, owing to revision of rating curve above 500 second-feet.

KICKAPOO RIVER AT GAYS MILLS, WIS.

LOCATION.—In sec. 28, T. 10 N., R 4 W., at highway bridge immediately below Norwood Mill, in Gays Mills, Crawford County, 25 miles above mouth of river and 2 miles below mouth of Tainter Creek, which enters from right.

DRAINAGE AREA.—629 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale, 1 inch=6 miles.

RECORDS AVAILABLE.—December 25, 1913, to September 30, 1917.

GAGE.—Chain gage fastened to downstream side of bridge; read by N. T. Norwood.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge at medium and high-water stages; low-water measurements made by wading a short distance downstream from gage.

CHANNEL AND CONTROL.—Bed composed of rock covered by a deposit of sand; banks at gage section fairly high and not subject to overflow at ordinary high-water stages. Control at the head of small rapids about 300 feet below gage; probably not permanent; the plotting of the discharge measurements indicates that at a stage of about 2 feet on the gage the control is changed to some point below, causing a reversal in the curve.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 15.05 feet March 24 (discharge about 6,300 second-feet); minimum discharge, about 160 second-feet, February 10.

1914–1917: Maximum discharge recorded March 24, 1917; minimum discharge, about 100 second-feet, last part of January, 1915.

ICE.—Stage-discharge relation seriously affected by ice.

REGULATION.—Mills at Gays Mills immediately above station, at Soldiers Grove, 7 miles upstream, and at several points above Soldiers Grove use comparatively little storage, so that the recorded flow past the station represents nearly the natural conditions. During low stages a small diurnal fluctuation is observed at the gage.

ACCURACY.—Stage-discharge relation not permanent. Rating curve used October 1 to March 20, well defined between 211 and 485 second-feet; fairly well defined between 485 and 1,340 second-feet; extended and subject to error above 1,340 second-feet. Curve used March 21 to September 30, poorly defined between 300 and 2,200 second-feet; extended and subject to error above and below these limits. Gage read to quarter tenths twice a day. Daily discharge ascertained by applying mean daily gage height to rating table except for period when stage-discharge relation was affected by ice, for which period it was ascertained by applying to rating table mean daily gage height corrected for effect of ice by discharge measurements, observer's notes, and weather records. Open-water records fair; winter records subject to error.

Discharge measurements of Kickapoo River at Gays Mills, Wis., during the year ending Sept. 30, 1917.

TURKEY RIVER AT GARBER, IOWA.

LOCATION.—In sec. 36, T. 92 N., R. 4 W., at single-span highway bridge at Garber, Clayton County, about 800 feet above mouth of Wayne Creek, which enters from right.

DRAINAGE AREA.—1,530 square miles (measured on map issued by United States Geological Survey; scale, 1 to 500,000).

RECORDS AVAILABLE.—August 29, 1913, to November 29, 1916, except October 1, 1914, to March 30, 1915. Station discontinued November 30, 1916.

GAGE.—Chain gage attached to handrail on downstream side of bridge; read once daily by E. J. Prolow.

DISCHARGE MEASUREMENTS.—Make from bridge, or by wading.

CHANNEL AND CONTROL.—Bed is composed of sand and mud; channel shifting. Right bank high and not subject to overflow; left bank will be overflowed only at extreme high stage or at gage height about 21 feet.

EXTREMES OF STAGE.—The highest stage within the last 20 years probably occurred May 18, 1902, when a stage representing about 23.7 feet referred to the gage datum was reached, as indicated by the highwater marks on A. F. Grafe's residence in Garber.

ICE.—Stage-discharge relation affected by ice, observations discontinued.

REGULATION.—An electric-light plant and gristmill at Elkader probably cause a slight daily fluctuation.

Data inadequate for determining daily or monthly discharge.

The following discharge measurement was made by C. Herlofson:

November 23, 1916: Gage height, 3.86 feet; discharge, 302 second-feet.

Daily gage height, in feet, of Turkey River at Garber, Iowa, for the period Oct. 1 to Nov. 29, 1916.

MAQUOKETA RIVER BELOW NORTH FORK OF MAQUOKETA RIVER, NEAR MAQUOKETA, IOWA.

Location.—In the southwest corner of the NE. ¼ sec. 17, T. 84 N., R. 3 E., at Bridgeport Bridge, about 3 miles northeast of Maquoketa, Jackson County, 1,200 feet above mouth of Mill Creek and 2 miles below mouth of North Fork of Maquoketa River.

Drainage area.—1,600 square miles (measured on map issued by United States Geological Survey, scale, 1 to 500,000). Drainage area at mouth, 1,960 square miles.

Records available. September 1, 1913, to September 30, 1917, except October, 1914, to March 20, 1915, when station was temporarily discontinued.

Gage.—Chain gage attached to downstream handrail of bridge 100 feet from right abutment; read by John Strodthoff.

Discharge measurements.—Make from bridge to which gage is attached.

Channel and control.—Bed of stream composed of sand; shifting. Two channels at all stages except above 12-foot stage above which there is overflow under pile-trestle approach on the left side.

Extremes of discharge.—Maximum stage recorded during year, 16.8 feet at 1.30 p. m., June 13 (discharge, 11,800 second-feet); minimum stage recorded, 1.65 feet, November 15 (discharge, 296 second-feet).

Prior to 1917: Maximum stage about 23.5 feet, probably in 1905 (discharge, about 24,300 second-feet).

Diversions.—None.

Regulation.—None.

Accuracy.—Stage-discharge relation changed probably during high water March 10-14. Rating curves used before and after the change well defined between 300 and 20,000 second-feet. Gage read once daily to hundredths. Daily discharge, except as noted below ascertained by applying daily gage height to rating table. Stage-discharge relation affected by ice December 14 to March 9; determination of discharge based on observer's notes and weather records. Open-water records good; winter records roughly approximate.

Discharge measurements of Maquoketa River below North Fork of Maquoketa River, near Maquoketa, Iowa, during the year ending Sept. 30, 1917.

ROCK RIVER AT AFTON, WIS.

LOCATION.—On line between secs. 22 and 27, T. 2 N., R. 12 E., at highway bridge in Afton, Rock County, about 9 miles above Illinois State line. Bass Creek enters from right about three-quarters of a mile below station.

DRAINAGE AREA.—3,190 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

RECORDS AVAILABLE.—February 5, 1914, to September 30, 1917.

GAGE.—Chain gage fastened to the downstream side of bridge; read by Albert Engelke.

DISCHARGE MEASUREMENTS.—Made from the downstream side of bridge, or by wading.

CHANNEL AND CONTROL.—Banks medium high, and will not be overflowed to any extent at flood stages. Bed composed of gravel and clean silt; practically permanent. Control not well defined.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 8.90 feet at 4 p. m. April 1 (discharge, 8,910 second-feet); minimum discharge, 555 second-feet, February 11.

1914–1917: Maximum stage recorded, 9.88 feet at 4 p. m., September 13, 1915 (discharge, 10,300 second-feet); minimum stage recorded, 0.5 foot at 7 a. m. August 16, 1914 (discharge, about 459 second-feet).

ICE.—Stage-discharge relation seriously affected by ice.

REGULATION.—Operation of power plants at Janesville and above causes fluctuations at the gage during low stages.

ACCURACY.—Stage-discharge relation permanent except as affected by ice. Rating curve well defined between 638 and 10,500 second-feet. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table, except for periods of ice effect, for which it was ascertained by applying to rating table mean daily gage height corrected for effect of ice by means of discharge measurements, observer's notes, and weather records. Open-water records good; winter records fair.

Discharge measurements of Rock River at Afton, Wis., during the year ending Sept. 30, 1917.

ROCK RIVER AT ROCKFORD, ILL.

LOCATION.—In sec. 34, T. 44 N., R. 1 E., at highway bridge at Nelson Avenue, Rockford, Winnebago County, about 1 mile below mouth of Kent Creek.

DRAINAGE AREA.—6,520 square miles.

RECORDS AVAILABLE.—July 30, 1914, to September 30, 1917.

GAGE.—Chain gage attached to upstream side of bridge; read by Winston Burrows.

DISCHARGE MEASUREMENTS.—Made from upstream side of bridge.

CHANNEL AND CONTROL.—Coarse gravel and rock; may shift in high stages.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 7.8 feet June 21 to 23 (discharge, 13,700 second-feet); minimum stage, 1.70 feet at 5.30 p. m. September 30 (discharge, 1,180 second-feet).

1914–1917: Maximum stage recorded, 15.5 feet February 15, 1915 (discharge not determined because of backwater from ice); maximum open-water stage recorded, 13.0 feet March 30 and 31, 1916 (discharge, 32,000 second-feet); minimum stage, 0.82 foot, August 9, 1914 (discharge, 483 second-feet).

ICE.—Stage-discharge relation seriously affected by ice.

REGULATION.—Operation of power plant at dam 2 miles upstream in city of Rockford causes slight fluctuation at gage.

ACCURACY.—Stage-discharge relation practically permanent except as affected by ice. Rating curve fairly well defined between 1,450 and 32,000 second-feet. Gage read to hundredths twice daily. Fluctuation at gage only slight. Daily discharge ascertained by applying mean daily gage height to rating tables, except for period when stage-discharge relation was affected by ice, for which it was determined from gage heights, observer's notes, weather records, and records of flow of Rock River at Afton, Wis. Open-water records good for medium and high stages; probably somewhat too large for low stages, as gage readings were taken during day when flow, owing to regulation at dam, is somewhat greater than during night; winter records poor.

The following discharge measurement was made by H. C. Beckman:

August 29, 1917; Gage height: 2.47 feet; discharge, 1,950 second-feet.

Daily discharge, in second-feet, of Rock River at Rockford, Ill., for the year ending Sept. 30, 1917.

ROCK RIVER AT LYNDON, ILL.

LOCATION.—In sec. 21, T. 20 N., R. 5 E., at highway bridge known as Lyndon Bridge, in eastern part of Lyndon, Whiteside County; about 10 miles above Rock Creek and 20 miles below dam at Sterling.

DRAINAGE AREA.—9,010 square miles.

RECORDS AVAILABLE.—November 24, 1914, to September 30, 1917.

GAGE.—Chain gage attached to bridge; read by John Shepard.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge.

CHANNEL AND CONTROL.—Gravel; may shift.

Extremes of discharge.—Maximum stage recorded during year, 15.2 feet March 14 (discharge not determined because of backwater from ice); maximum open-water stage recorded, 12.6 feet at 7 a. m. June 14 (discharge, 21,400 second-feet); minimum stage recorded, 4.6 feet at 5 p. m. September 2 (discharge, 1,170 second-feet).

1915–1917: Maximum stage recorded, 18.0 feet January 22 and 23, 1916 (discharge not determined because of backwater from ice); maximum open-water stage recorded, 17.0 feet March 28, 1916 (discharge, 39,500 second-feet). Minimum discharge recorded, 1,170 second-feet at 5 p. m. September 2, 1917.

Ice.—Stage-discharge relation seriously affected by ice.

Diversions.—Water is diverted at Sterling dam to feed Illinois and Mississippi canal; probably averages about 100 second-feet.

Regulation.—Operation of power plant in city of Sterling causes fluctuation at gage. Fluctuations slight except during low stages.

Accuracy.—Stage-discharge relation changed during March; affected by ice during winter. Rating curves well defined. Gage read to hundredths twice daily. Diurnal fluctuation at gage not large. Daily discharge ascertained by applying mean daily gage height to rating table, except for period when stage-discharge relation was affected by ice, for which it was ascertained from gage heights, observer's notes, weather records, and record of flow of Rock River at Rockford, Ill., and Afton, Wis. Records good for medium and high stages and fair for very low stages during open-water periods; poor for winter period.

Daily discharge measurements of Rock River at Lyndon, Ill., during the year ending Sept. 30, 1917.

[Made by H. C. Beckman.]

YAHARA RIVER NEAR EDGERTON, WIS.

Location.—At highway bridge in sec. 3, T. 4 N., R. 11 W., 1 mile above mouth of Badfish River (coming in from right) and about 5 miles southwest of Edgerton, Rock County.

Drainage area.—380 square miles (measured on map issued by Wisconsin and Geological History Survey, edition of 1911; scale, 1 inch=6 miles).

Records available.—September 27, 1916 to November 23, 1917, when station was discontinued.

Gage.—Friez water-stage recorder in a wooden well fastened to the right-hand downstream wing wall.

Discharge measurement.—Made from downstream side of highway bridge.

Channel and control.—Bed composed of gravel, control is head of rapids a short distance downstream. During the summer months grass grows in the channel and on the control affecting stage-discharge relation.

Extremes of discharge.—Maximum stage recorded, 3.13 feet 2 a. m., June 13, 1917 (discharge, 1,390 second-feet); minimum stage, 1.64 feet 5 p. m., October 8, 1916 (discharge, about 118 second-feet).

Ice.—Stage-discharge relation seriously affected by ice.

Accuracy.—Stage-discharge relation not permanent; affected by grass and ice. Rating curve well defined between 290 and 780 second-feet; extended and subject to error above and below these limits. Operation of water-stage recorder satisfactory throughout the year. Daily discharge ascertained by discharge integrator; shifting-control method used September 27 to October 8, 1916, and June 1 to October 31, 1917; discharge December 14 to March 21 ascertained from discharge measurements, gage heights, and weather records. Open-water records good; winter records subject to error.

Discharge measurements of Yahara River near Edgerton, Wis., for the period Sept. 28, 1916, to November 23, 1917.

PECATONICA RIVER AT DILL, WIS.

Location.—In sec. 6, T. 1 N., R. 6 E., at Illinois Central Railroad bridge at Dill (Ramona post office), Green County, about 1 mile below junction of east and west branches of Pecatonica River and 9 miles above Illinois State line.

Drainage area.—959 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

Records available.—February 9, 1914, to September 30, 1917.

Gage.—Chain gage fastened to downstream side of bridge; prior to August 2, 1916, vertical staff gage on left abutment. Gage read by W. C. Shadewaldt and S. A. Frank.

Discharge measurements.—At low and medium stages made from upstream side of highway bridge about 400 feet above the gage; during extremely high water considerable water overflows to left of highway bridge and measurements are made from railroad bridge to which the gage is attached.

Channel and control.—Bed composed of sand and silt; undoubtedly shifting. Banks are only of medium height and are overflowed at flood stages. Except during extreme flood stages all the water passes under the bridge to which the gage is fastened. There is little fall in the river below the gage and no well-defined control.

Extremes of discharge.—Maximum stage recorded during year, 12.6 feet at 7 a. m. March 15 (discharge, about 4,500 second-feet); minimum discharge, 260 second-feet January 20–22.

1914–1917: Maximum stage, 19.1 feet March 27, 1916, determined from flood marks by leveling (discharge, about 13,100 second-feet); minimum discharge, January 20–31, 1915 (estimated mean discharge 245 second-feet).

Ice.—Stage-discharge relation affected by ice.

Regulation.—Operation of dams at Argyle, on the East Branch of Pecatonica River, and at Darlington, on the West Branch of Pecatonica River, cause little if any diurnal fluctuation at the gage.

Accuracy.—Stage-discharge relation changed somewhat during the period between June and September; also affected by ice. Rating curve used October 1 to June 30 well defined between 350 and 1,520 second-feet and fairly well defined between 1,520 and 6,000 second-feet; extension of the curve above 6,000 second-feet is based on the flow of Pecatonica River at Freeport, Ill. Discharge, June 14 to September 30 determined by shifting-control method; discharge for rest of open-water period ascertained by applying mean daily gage height to rating table; for period of ice effect determined by applying to rating table mean daily gage height corrected by means of discharge measurements, observers' notes, and weather records. Open-water records goods except those for July to September, which are only fair; winter records subject to error.

Discharge measurements of Pecatonica River at Dill, Wis., during the year ending Sept. 30, 1917.

PECATONICA RIVER AT FREEPORT, ILL.

LOCATION.—In sec. 32, T. 27 N., R. 8 E., at highway bridge at Hancock Avenue, half a mile east of Illinois Central Railroad station at Freeport, Stephenson County, and 2 miles above mouth of Yellow Creek.

DRAINAGE AREA.—1,330 square miles.

RECORDS AVAILABLE.—September 10, 1914, to September 30, 1917.

GAGE.—Chain gage attached to upstream side of bridge; read by W. C. Krueger.

DISCHARGE MEASUREMENTS.—Made from upstream side of bridge.

CHANNEL AND CONTROL.—Bed composed of sand and silt; likely to shift. Left bank is of only medium height and is overflowed during high water. At stages above about 16.0 feet part of the flow passes over the left bank and through East Freeport.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 16.0 feet at 8 a. m. March 16 (discharge, 6,140 second-feet); minimum stage, 3.5 feet August 31 and September 2 (discharge, 239 second-feet).

1914–1917: Maximum stage recorded, 19.4 feet March 28, 1916 (discharge, 17,000 second-feet); minimum discharge recorded August 31 and September 2, 1917.

ICE.—Stage-discharge relation seriously affected by ice.

REGULATION.—A dam and power plant three-fourths mile upstream regulate flow past gage. Only slight diurnal fluctuation is noticeable.

ACCURACY.—Stage-discharge relation changed, probably after high water in June; affected by ice during winter. Rating curve used to June 30 well defined; curve used August 21 to September 30 fairly well defined. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table; shifting-control method used July 1 to August 20. Records good for medium and high stages and fair for low stages during open-water periods, winter records poor.

The following discharge measurement was made by H. C. Beckman:

August 31, 1917: Gage height, 3.50 feet; discharge, 233 second-feet.

Daily discharge, in second-feet, of Pecatonica River at Freeport, Ill., for the year ending Sept. 30, 1917.

SUGAR RIVER NEAR BRODHEAD, WIS.

LOCATION.—In sec. 26, T. 2 N., R. 9 E., at highway bridge 2 miles southwest of Brodhead, Green County, about 12 miles above Illinois State line. Jordan Creek enters from right about 2 miles below station, and Little Jordan Creek, also from right, about 4 miles above.

DRAINAGE AREA.—529 square miles (measured on map issued by Wisconsin Geological and Natural History Survey, edition of 1911; scale, 1 inch=6 miles).

RECORDS AVAILABLE.—February 7, 1914, to September 30, 1917.

GAGE.—Chain gage attached to downstream side of bridge; read by Arthur Christensen.

DISCHARGE MEASUREMENTS.—Made from upstream side of bridge or by wading.

CHANNEL AND CONTROL.—Bed composed of sand and gravel; control not well defined. Right bank of medium height; rarely overflowed. Left bank at the gage overflowed at stage of about 7 feet on the gage.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 6.48 feet at 4.30 p. m. June 13 (discharge, 2,710 second-feet); minimum discharge about 85 second-feet February 11.

1914–1917: Maximum stage recorded, 11.4 feet, September 13, 1915 (discharge about 13,000 second-feet); minimum stage recorded, 0.4 foot at 10 a. m., Sunday, August 30, 1914, when water was undoubtedly being held at the dam (discharge, determined from extension of the rating curve, about 74 second-feet).

ICE.—Stage-discharge relation affected by ice.

ACCURACY.—Stage-discharge relation not permanent; control changed somewhat by floods. Two rating curves as used for 1917, both only fairly well defined between 228 and 4,500 second-feet. Gage read daily to quarter-tenths. Daily discharge ascertained by applying mean daily gage height to rating table, except for periods of ice effect, for which it is ascertained by applying to rating table mean daily gage height corrected by means of discharge measurements, observer's notes, and weather records. Open-water records fair; winter records roughly approximate.

IOWA RIVER AT MARSHALLTOWN, IOWA.

LOCATION.—In T. 84 N., R. 18 W., at Third Avenue highway bridge, 1 mile north of Marshalltown, Marshall County, and about a mile below site of old gaging station.

DRAINAGE AREA.—1,380 square miles (measured on map issued by United States Geological Survey; scale, 1 to 500,000).

RECORDS AVAILABLE.—May 21, 1915, to September 30, 1917; February 23, 1903, to August 8, 1903, for old site a mile above present station.

GAGE.—Chain gage attached to downstream handrail of bridge, 60 feet from right pier; read by B. S. Beehrle.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge, to which gage is attached.

CHANNEL AND CONTROL.—Bed of stream sandy and subject to change; right bank not subject to overflow; left bank will be overflowed at stages above 13 feet.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 14.4 feet March 27 (discharge, 9,640 second-feet); minimum stage recorded, 2.32 feet October 9 (discharge, 56 second-feet).

ICE.—Stage-discharge relation seriously affected by ice; observations discontinued during winter.

ACCURACY.—Stage-discharge relation not permanent. One rating curve, well defined below 2,000 second-feet, used during 1917. Gage read once daily to hundredths. Daily discharge ascertained by applying daily gage height to rating table. Open-water records good.

IOWA RIVER AT IOWA CITY, IOWA.

Location.—In T. 79 N., R. 6 W. at highway bridge about 500 feet below Chicago, Rock Island & Pacific Railway main-line bridge; about three-quarters of a mile below Iowa State University's power plant, three-quarters of a mile downstream from old gaging station, which was at county highway bridge a short distance above dam.

Drainage area.—3,140 square miles (measured on map issued by United States Geological Survey; scale, 1 to 500,000).

Records available.—October 30, 1913, to September 30, 1917, at present site; June 11, 1903, to July 21, 1906, for old gaging station.

Gage.—Chain gage, attached to upstream handrail of bridge about 40 feet from left-hand end of first span from left bank; read by Ray Stramp, C. P. McGrath, and A. Kostal.

Discharge measurements.—Made from bridge to which gage is attached, or from a boat about 1,000 feet below highway bridge.

Channel and control.—Bed composed of sand; subject to change. Right bank high and will not be overflowed; left bank will be overflowed at high stage under a pile trestle approach to the bridge and beyond the left end of the approach at extremely high stage.

Extremes of discharge.—Maximum stage recorded during year, 8.8 feet June 7 (discharge, 6,950 second-feet); gage not read during high water June 9-22. Minimum stage recorded, −.50 foot December 26 (discharge, about 10 second-feet). Maximum stage ever recorded, about 15 feet (old gage) night of June 2-3, 1903 (discharge, about 20,000 second-feet); minimum discharge, about 10 second-feet December 26, 1916.

Ice.—Stage-discharge relation affected by ice; observations discontinued during winter.

Regulation.—Considerable diurnal fluctuations at low stages owing to operation of power plant above station.

Accuracy.—Stage-discharge probably permanent during year. Rating curve well defined between 142 and 11,000 second-feet. Gage read once daily to half-tenths. Daily discharge, except as noted below, ascertained by applying daily gage height to rating table. No gage readings available October 1-3, March 15 to April 10, and June 9-22; discharge estimated from record of discharge at Marshalltown. Records for periods in which discharge was estimated and in which it was less than 142 second-feet fair; records for periods of low water with marked diurnal fluctuation are of doubtful value; other records excellent.

Discharge measurements of Iowa River at Iowa City, Iowa, during the year ending Sept. 30, 1917.

IOWA RIVER AT WAPELLO, IOWA.

LOCATION.—In sec. 27, T. 74 N., R. 3 W., at highway bridge about half a mile from railroad station at Wapello, Louisa County, and 20 miles from mouth of Iowa River. No large tributaries enter near station.

DRAINAGE AREA.—At gaging station, 12,480 square miles; at mouth, 12,600 square miles (measured on map issued by United States Geological Survey; scale, 1 to 500,000).

RECORDS AVAILABLE.—February 26, 1915, to September 30, 1917.

GAGE.—Chain gage attached near center of first span from right abutment; read by C. W. Warren.

DISCHARGE MEASUREMENTS.—Made from bridge to which gage is attached.

CHANNEL AND CONTROL.—Bed composed of sand and gravel; shifts slightly. Right bank high and will not be overflowed; levee along left bank might break or be overtopped at extremely high stages.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 13.2 feet, March 29 (discharge, 52,000 second-feet); minimum discharge, 400 second-feet December 15–17. Maximum known stage prior to 1917, about 14.3 feet about April 3, 1912 (discharge, about 58,000 second-feet). The flood of June, 1892, was much higher.

ICE.—Stage-discharge relation seriously affected by ice.

ACCURACY.—Stage-discharge relation nearly permanent; one rating curve used during 1917, well defined throughout. Gage read once daily to hundredths. Daily discharge, except as noted below, ascertained by applying daily gage height to rating table. Stage-discharge relation affected by ice December 14 to March 9; discharge ascertained from one discharge measurement, observer's notes, gage heights, and weather records. Open-water records excellent; winter records fair.

Discharge measurements of Iowa River at Wapello, Iowa, during the year ending Sept. 30, 1917.

CEDAR RIVER AT JANESVILLE, IOWA.

Location.—In sec. 35, T. 91 N., R. 14 W., at Illinois Central Railroad bridge about a quarter of a mile below highway bridge and 3 miles above junction with Shellrock River.

Drainage area.—1,660 square miles (measured on map issued by United States Geological Survey; scale, 1 to 500,000).

Records available.—April 26, 1905, to September 30, 1906; May 28, 1915, to September 30, 1917.

Gage.—Chain gage attached to upstream guardrail of bridge about the middle of left span; read by James Townsend.

Discharge measurements.—Made from upstream side of railroad bridge.

CHANNEL AND CONTROL.—Bed composed of gravel; slightly shifting. Banks high and not subject to overflow.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 13.6 feet 8 a. m., March 24 (discharge, 21,200 second-feet); minimum stage recorded, 0.78 foot December 10, (discharge, 181 second-feet.)

1905–06 and 1915–1917: Maximum discharge, 22,600 second-feet March 28, 1906; minimum stage recorded, 0.75 foot, November 3, 1915 (discharge, 173 second-feet).

ICE.—Stage-discharge relation seriously affected by ice; observations discontinued during winter.

REGULATION.—May be slight diurnal fluctuation of water level owing to operation of power plant at Waverly, 9 miles above station.

ACCURACY.—Stage-discharge relation nearly permanent. Rating curve well defined throughout. Gage read once daily to hundredths. Daily discharge ascertained by applying daily gage height to rating table. Records excellent.

CEDAR RIVER AT CEDAR RAPIDS, IOWA.

LOCATION.—In T. 83 N., R. 7 W., in central part of Cedar Rapids, Linn County, about half a mile below dam, between electric-railroad bridge and Seventh Avenue combination railroad and footbridge.

DRAINAGE AREA.—At gaging station, 6,640 square miles; at junction with Iowa River, 7,930 square miles (measured on map issued by United States Geological Survey; scale, 1 to 500,000).

RECORDS AVAILABLE.—October 26, 1902, to September 30, 1917.

GAGE.—Inclined staff gage fastened to posts driven in right bank of the river in rear of plant of the Iowa Windmill & Pump Co.; read by R. S. Toogood. Elevation of zero of gage from Northwestern Railroad levels, 723.03 feet above sea level.

DISCHARGE MEASUREMENTS.—Made from different bridges in the vicinity of the gage, according to the stage.

CHANNEL AND CONTROL.—Bed composed of rock and gravel; free from vegetation and practically permanent.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 17.2 feet at 6 p. m., March 26 (discharge, 54,200 second-feet); minimum open-water stage recorded during year, 2.9 feet October 9–17 (discharge, 740 second-feet); minimum winter discharge much less.

1902–1917: Maximum stage recorded, 17.2 feet April 1, 1912, and March 26, 1917 (discharge, 54,200 second-feet); minimum open-water stage recorded, 2.5 feet July 24–28, 1911 (discharge, 410 second-feet); minimum during period of ice effect in December, 1916, probably much less. Greatest known flood probably occurred in June, 1851, when the maximum stage was about 20 feet, and the discharge about 65,000 second-feet.

ICE.—Stage-discharge relation affected by ice, except in very mild winters, when the swift current and the proximity to the power plant keep the measuring section open.

REGULATION.—Power has been developed at the new dam above the gaging station during 1917. There is no direct evidence yet of effect on gage readings. There is no dam for a long distance below Cedar Rapids and no backwater at gaging station.

ACCURACY.—Stage-discharge relation nearly permanent. Rating curve well defined. Gage read once daily, to tenths. Daily discharge ascertained by applying daily-gage height to rating table. Stage-discharge relation affected by ice December 14 to March 18; discharge estimated as 70 per cent of discharge at Wapello. Open-water records excellent; winter records fair.

COOPERATION.—Gage-height record furnished by United States Weather Bureau.

Discharge measurements of Cedar River at Cedar Rapids, Iowa, during the year ending Sept. 30, 1917.

SHELLROCK RIVER NEAR CLARKSVILLE, IOWA.

LOCATION.—In T. 92 N., R. 16 W., at highway bridge 1¼ miles northwest of Clarksville, Butler County, and about 25 miles above junction with Cedar River. No large tributaries enter for several miles up and down stream.

DRAINAGE AREA.—1,660 square miles at station and 2,680 square miles at junction with Cedar River (measured on map issued by United States Geological Survey; scale, 1 to 500,000).

RECORDS AVAILABLE.—May 28, 1915, to September 30, 1917.

GAGE.—Chain gage attached to handrail on upstream side of bridge 75 feet from right abutment; read by Mrs. H. H. Sherburne.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge to which gage is attached.

CHANNEL AND CONTROL.—Bed composed of rock and sand; probably permanent. Right bank high and will not be overflowed; left bank will probably be overflowed during extreme high stage.

EXTREMES OF DISCHARGE.—Maximum stage during year about 14.7 feet, March 22 (probably affected by ice); minimum stage recorded since station was established 1.15 feet October 23, 1916 (discharge, 125 second-feet). In April, 1907, a stage of about 16.5 feet was reached (discharge, about 19,000 second-feet).

ICE.—Stage-discharge relation affected by ice November 14–18, 25–26 and December 9 to about March 22; observations discontinued during winter.

ACCURACY.—Stage-discharge relation practically permanent, except as affected by ice. Rating curve well defined between 200 and 10,000 second-feet; not well defined outside these limits. Gage read once daily to hundredths. Daily discharge ascertained by applying daily gage height to rating table; estimated for period of ice effect. Records excellent except those for extremely low, and high stages, which are fair; winter records roughly approximate.

SKUNK RIVER AT COPPOCK, IOWA.

LOCATION.—In T. 74 N., R. 8 W., at highway bridge one-eighth mile above Chicago, Burlington & Quincy Railroad bridge and a quarter of a mile above junction with Crooked Creek.

DRAINAGE AREA.—2,890 square miles (measured on map issued by United States Geological Survey; scale, 1 to 500,000).

RECORDS AVAILABLE.—October 21, 1913, to September 30, 1917.

GAGE.—Chain gage attached to downstream side of bridge; read by J. W. Ricks.

DISCHARGE MEASUREMENTS.—Made from bridge to which gage is attached.

CHANNEL AND CONTROL.—Bed composed of gravel and sand; channel shifting.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 17.5 feet June 14 (discharge, 15,700 second-feet); minimum discharge recorded, 52 second-feet October 17.

Maximum stage prior to 1917 about 24 feet (discharge, 30,000 second-feet) about the end of May, 1903.

ICE.—Stage-discharge relation seriously affected by ice; observations discontinued during winter.

ACCURACY.—Stage-discharge relation changed during the year, requiring the use of three rating curves applicable October 1–11, October 15 to November 26, and November 30 to September 30. The second rating curve, used during the rebuilding of piers of the Chicago, Burlington & Quincy Railroad bridge below the station, is not well defined; the other two curves are well defined. Discharge interpolated October 12–14 and November 27–29. Gage read once daily to hundredths. Daily discharge ascertained by applying daily gage height to rating table. Open-water records excellent.

Discharge measurements of Skunk River at Coppock, Iowa, during the year ending Sept. 30, 1917.

SKUNK RIVER AT AUGUSTA, IOWA.

LOCATION.—In T. 69 N., R. 4 W., at highway bridge about one-third mile from Augusta post office, Des Moines County, and 12.2 miles from mouth of Skunk River, where it empties into pond of Mississippi River Power Co., 32.2 miles above dam at Keokuk, Iowa.

DRAINAGE AREA.—At gaging station 4,200 square miles; at mouth 4,350 square miles (measured on map issued by United States Geological Survey; scale, 1 to 500,000).

RECORDS AVAILABLE.—September 30 to November 15, 1913; May 27, 1915, to September 30, 1917.

GAGE.—Chain gage attached to downstream handrail of bridge about 95 feet from left abutment; read once daily by L. E. Williamson. Staff gage attached to downstream left side of middle pier, used by engineers of the Hydraulic Engineering Co. of Maine during 1913; datum of gage about 0.73 foot higher than that of chain gage; taken out by ice in spring of 1914.

DISCHARGE MEASUREMENTS.—Made from bridge to which gage is attached.

CHANNEL AND CONTROL.—Bed of stream sandy and subject to change; right bank high and will not be overflowed; left bank will only be overflowed at extremely high stage; remains of old mill dam 600 feet below gage will probably make stage-discharge relation permanent. The riffle at the dam causes a drop of 3 feet at medium low stage. Backwater from the Mississippi can not occur oftener than once in about 50 years.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year 17.0 feet June 7; minimum stage recorded, 1.20 feet September 24.

Maximum stage prior to 1917 approximately 21 feet about June 1, 1903 (discharge, nearly 40,000 second-feet); minimum discharge recorded, 63 second-feet November 10, 1913; absolute minimum discharge at this station probably 25 second-feet or less.

ICE.—Stage-discharge relation affected by ice December 14 to March 12.

Data inadequate for determination of discharge.

Discharge measurements of Skunk River at Augusta, Iowa, during the year ending Sept. 30, 1917.

[Made by C. Herlofson.]

DES MOINES RIVER AT KALO, IOWA.

Location.—In sec. 17, T. 88 N., R. 28 W., at highway bridge at Kalo, Webster County, about 1½ miles east of Otho, a station on Minneapolis & St. Louis Railroad, and 1½ miles above mouth of Holiday Creek, which enters from left.

Drainage area.—4,170 square miles (measured on map issued by United States Geological Survey, scale 1 to 500,000).

Records available.—October 18, 1913, to September 30, 1917, except October, 1914, to March 21, 1915, when the station was temporarily discontinued.

Gage.—Chain gage attached to downstream side of bridge in middle of right span; read by S. C. Fuller.

Discharge measurements.—At high stages made from bridge to which gage is attached; at low stages by wading.

Channel and control.—No well-defined control; channel consists of gravel and is fairly permanent; point of zero flow estimated to be at gage height −1.0 foot.

Extremes of discharge.—Maximum stage recorded during year 12.9 feet March 22 (discharge, 17,100 second-feet); minimum stage recorded since establishment of station, 0.25 foot October 12, 1916 (discharge, 66 second-feet).

1913–1917: Maximum stage recorded, 14.0 feet May 30, 1915 (discharge, 18,500 second-feet).

Ice.—Stage-discharge relation affected by ice November 14–18, 24–26, December 9 to March 21; observations discontinued during winter.

Accuracy.—Stage-discharge relation permanent throughout year except as affected by ice. Rating curve well defined between 200 and 12,000 second-feet; extended below 200 second-feet and only roughly approximate. Gage read once daily to quarter tenths. Daily discharge ascertained by applying daily gage height to rating table; estimated November 14–18, 24–26, because of ice. Records excellent except those below 200 second-feet, which are roughly approximate.

Discharge measurements of Des Moines River at Kalo, Iowa, during the year ending Sept. 30, 1917.

DES MOINES RIVER AT DES MOINES, IOWA.

LOCATION.—In T. 78 N., R. 24 W., at Walnut Street Bridge at Des Moines, Polk County, about one-third mile above mouth of Raccoon River and 205 miles above mouth of Des Moines River.

DRAINAGE AREA.—6,180 square miles. Effective area at high stages, including Raccoon River, 9,770 square miles (measured on map issued by United States Geological Survey; scale 1 to 500,000).

RECORDS AVAILABLE.—October 2, 1902, to August 3, 1903; October 1, 1914, to September 30, 1917, at the Walnut Street Bridge. From May 26, 1905, to July 20, 1906, records were collected at the Interurban Bridge near Highland Park, about 5 miles above present station. The United States Weather Bureau has maintained a gage at the Locust Street Bridge from July 1, 1897, to January, 1912; and at the Walnut Street Bridge from January, 1912, to September 30, 1917.

GAGE.—The original Weather Bureau gage is a staff gage at the Locust Street Bridge; one block above the Walnut Street Bridge. In January, 1912, a Friez water-stage recorder was installed by the United States Weather Bureau in and near the south end of the second pier from the east abutment of the Walnut Street Bridge. This gage is set to read the same as Locust Street gage. A copper float in a 9-inch pipe connects with the register at the top, which is graduated to record graphically stages from 0 to 33 feet. Gage zero is 774.74 feet above sea level.

DISCHARGE MEASUREMENTS.—Made at any one of several bridges below the power dam, according to the stage. Channel satisfactory for accurate measurements.

CHANNEL AND CONTROL.—A sheet-piling dam was constructed about 300 feet above the old mouth of Raccoon River about September, 1913. This dam, called a "beauty dam," is for the purpose of raising the low-water stage of the river a few feet and thus improving the appearance of the river through the park along the bank. The pooled water from this dam extends past the gage to the power dam at low water. The dam thus forms a fairly permanent control at low stages. It is drowned out at stages of 8 to 10 feet, depending on the stage in Raccoon River. Dam is now in poor repair and the stage-discharge relation has been affected thereby.

EXTREMES OF STAGE.—Maximum stage recorded during year, 16.1 feet June 10; minimum stage recorded, 1.3 feet in January.

1897–1917; maximum stage recorded, 22.6 feet, May 31, 1903; minimum stage recorded, 0.8 foot at various times.

ICE.—The effect of the power dam above the station is to improve the conditions of winter flow, but severe winters and occasional ice jams below the gage often seriously affect the stage-discharge relation.

REGULATION.—The Edison Power & Light Co.'s dam, about one-fourth mile above gage, causes slight diurnal fluctuation of stage. The dam is practically drowned out at a stage of 18 feet, although there is a perceptible ripple with a stage of 21 or 22 feet.

COOPERATION.—The gage-height records are furnished by the United States Weather Bureau.

Determinations of discharge withheld for additional data.

DES MOINES RIVER AT OTTUMWA, IOWA.

Location.—At Market Street Bridge, Ottumwa, Wapello County. No large tributary within several miles up or down stream.

Drainage area.—13,200 square miles (measured on map issued by the United States Geological Survey; scale, 1 to 500,000).

Records available.—Fragmentary high-water observations 1902–1916; daily records March 29 to September 30, 1917.

Gage.—Chain gage attached to downstream handrail of bridge. Staff gage painted on northeast face of north pier used prior to August 2, 1917.

Discharge measurements.—Made from Vine Street Bridge about 1,500 feet below gage.

Channel and control.—Channel probably fairly permanent.

Extremes of discharge.—Maximum stage recorded during the year, 16.5 feet June 11; minimum stage recorded, 1.5 feet September 25–30.

Maximum discharge since 1850 and probably in the last century occurred May 31, 1903, and exceeded 100,000 second-feet.

Ice.—Stage-discharge relation seriously affected by ice.

Cooperation.—Gage-height record obtained by the United States Weather Bureau.

Data inadequate for determination of discharge.

Discharge measurements of Des Moines River at Ottumwa, Iowa, for the period Sept. 18, 1914, to Sept. 30, 1917.

DES MOINES RIVER AT KEOSAUQUA, IOWA.

LOCATION.—In sec. 36, T. 69 N., R. 10 W., at county bridge, Keosauqua, Van Buren County, a quarter of a mile above old dam site and Government locks. No large tributary enters Des Moines River for several miles up or down stream.

DRAINAGE AREA.—At gaging station, 13,900 square miles; at mouth, 14,300 square miles (revised measurements made from map issued by United States Geological Survey; scale, 1 to 500,000).

RECORDS AVAILABLE.—May 30, 1903, to July 21, 1906; April 5 to December 31, 1910 (United States Engineer Corps); August 3, 1911, to September 30, 1917.

GAGE.—Chain gage attached to upstream handrail of bridge; read by Frank Schreckengast.

DISCHARGE MEASUREMENTS.—Made from bridge to which gage is attached.

CHANNEL AND CONTROL.—Channel shifts considerably at flood stages. Control is a gravel riffle about one-fourth mile below gage.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 18.45 feet June 14 (discharge, 60,500 second-feet); minimum stage recorded, 0.10 foot, several days in October (discharge, 330 second-feet).

Maximum stage since 1850 and probably in the last century, 27.9 feet June 1, 1903 (discharge, 97,000 second-feet); maximum stage June 1, 1851, about 24 feet (discharge, about 80,000 second-feet).

1903–1917: Minimum stage recorded, zero, August 28 to September 6, 1911 (discharge, 160 second-feet).

ICE.—Stage-discharge relation seriously affected by ice.

ACCURACY.—Stage-discharge relation fairly permanent for low and medium stages. Two fairly well defined rating curves were used. Gage read once daily to half-tenths. Stage-discharge relation affected by ice December 13 to March 9; discharge estimated from observer's notes and weather records. Open-water records good; winter records roughly approximate.

Discharge measurements of Des Moines River at Keosauqua, Iowa, during the year ending Sept. 30, 1917.

RACCOON RIVER AT VAN METER, IOWA.

LOCATION.—In SW. ¼ sec. 22, T. 78 N., R. 27 W., at highway bridge about one-third mile from railroad station, 1 mile below South Raccoon River, and 30 miles above junction of Raccoon River with Des Moines River.

DRAINAGE AREA.—At gaging station, 3,410 square miles; at mouth, 3,590 square miles (measured on map issued by United States Geological Survey, scale 1 to 500,000).

RECORDS AVAILABLE.—April 25, 1915, to September 30, 1917.

GAGE.—Chain gage attached to downstream handrail of bridge about 25 feet from right end of bridge; read by Fred Vreeland.

DISCHARGE MEASUREMENTS.—Made from bridge to which gage is attached.

Channel and control.—Bed composed of sand; subject to change. River divided into two channels at low and medium stages by an island; water surface slightly higher in the left channel than in the right at extreme low water; right bank high and not subject to overflow; left bank subject to overflow at a stage of about 13 feet. At extremely high stage this overflow will extend for several thousand feet beyond left end of bridge.

Extremes of discharge.—Maximum stage recorded during year, 17.5 feet June 7 (discharge, 31,800 second-feet); minimum stage, 1.83 feet October 12 and 17 (discharge, 64 second-feet).

1915–1917. Maximum stage recorded, June 7, 1917; minimum stage recorded 1.8 feet August 29, 1916 (discharge, 60 second-feet).

Ice.—Stage-discharge relation affected by ice November 14–20 and December 10 to March 19. Observations discontinued December 13 to March 13.

Accuracy.—Stage-discharge relation permanent throughout year. Rating curve well defined between 155 and 15,000 second-feet. Gage read to hundredths once daily. Daily discharge ascertained by applying gage height to rating table; estimated November 14–20 because of ice. Open-water records excellent, except those for extremely low stages, which are fair.

ILLINOIS RIVER AT PEORIA, ILL.

Location.—In sec. 2, T. 8 N., R. 8 E., at foot of Grant Street, Peoria, Peoria County, about 3½ miles above station formerly maintained at Peoria & Pekin Union Railroad bridge and 4½ miles above mouth of Kickapoo Creek.

Drainage area.—Not measured.

Records available.—March 8, 1910, to September 30, 1917; also March 10, 1903, to July 21, 1906, for station at Peoria & Pekin Union Railroad bridge.

Gage.—Vertical staff gage attached to wooden pile; read by employee of United States Army Engineers.

Discharge measurements.—Made from downstream side of Lower Free bridge, about 2 miles below gage.

Channel and control.—Bed of river, which forms control for medium and high stages, is mud and may shift. Dam at Copperas Creek probably forms control for lowest stages; permanent.

Extremes of discharge.—Maximum stage recorded during year, 18.4 feet June 15–17 (discharge, 34,800 second-feet); minimum stage, 10.0 feet October 1–4, 7–8, 10–18, and 20 (discharge, 10,000 second-feet).

1910–1917: Maximum stage recorded, 23.2 feet January 25, 1916 (discharge not determined because of backwater from ice); maximum open-water stage recorded, 22.4 feet March 30 to April 2, 1913 (discharge, 55,000 second-feet); minimum stage, 8.0 feet December 14, 1910 (discharge, 7,250 second-feet).

The highest known flood occurred in 1844, when a stage of about 26.6 feet on the present gage was reached.

Regulation.—The flow at this station includes the water diverted from Lake Michigan through the Chicago Drainage canal.

Accuracy.—Stage-discharge relation practically permanent; seriously affected by ice during the winters. Rating curve well-defined between 11,000 and 40,000 second-feet and fairly well defined beyond these limits. Gage read to half-tenths once daily. Daily discharge ascertained by applying daily gage height to rating table. Records good for open-water periods; poor for winter periods.

Cooperation.—Gage-height records furnished by the United States Engineer Corps.

Discharge measurements of Illinois River at Peoria, Ill., during the years ending Sept. 30, 1916–17.

KANKAKEE RIVER AT MOMENCE, ILL.

Location.—In sec. 24, T. 31, N., R. 13 E., at highway bridge in Momence, Kankakee County, half a mile below Chicago & Eastern Illinois Railroad bridge and 1½ miles above Tower Creek.

Drainage area.—2,340 square miles.

Records available.—February 22, 1905, to July 20, 1906; December 3, 1914, to September 30, 1917.

Gage.—Chain gage attached to bridge over left channel; read by Oscar Conrad.

Discharge measurements.—Made from upstream side of bridge across the two channels during medium and high stages, and by wading during low stages.

Channel and control.—Coarse gravel; practically permanent; river at gage divided into two channels by an island. Aquatic plants sometimes grow in bed of river during summer. Recent measurements show that there has been a change in the stage-discharge relation as expressed by the rating curve used prior to July 20, 1906.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 6.5 feet at 5 p. m., January 14 (discharge not determined because of backwater from ice); maximum open-water stage recorded, 3.5 feet April 6 and 7 (discharge, 4,372 second-feet); minimum stage, 1.67 feet September 29 and 30 (discharge, 534 second-feet).

1905–6 and 1915–17: Maximum stage recorded, 7.5 feet January 21, 1916 (discharge not determined because of backwater from ice); maximum open-water stage, 6.4 feet January 22, 1916 (discharge, estimated from extension of rating curve, 12,600 second-feet). Minimum discharge, 360 second-feet, July 13–20, 1906.

ACCURACY.—Stage-discharge relation permanent; seriously affected by ice during winter. Rating curve well defined below and fairly well defined above 3,100 second-feet. Gage read to hundredths twice daily until April 30 and once daily afterwards. Daily discharge ascertained by applying daily gage heights to rating table. Open-water records good; winter records roughly approximate.

Discharge measurements of Kankakee River at Momence, Ill., during the year ending Sept. 30, 1917.

[Made by H. C. Beckman.]

KANKAKEE RIVER AT CUSTER PARK, ILL.

Location.—In sec. 19, T. 32 N., R. 10 E., at Wabash Railroad bridge in Custer Park, Will County, about half a mile above Horse Creek and 15 miles below dam and power plant at Kankakee.

Drainage area.—4,870 square miles.

Records available.—November 6, 1914, to September 30, 1917.

Gage.—Chain gage attached to bridge; read by J. H. Swords.

Discharge measurements.—Made from downstream side of bridge.

Channel and control.—Solid rock strewn with boulders and gravel; right half of channel deep, with fissures in bed; left half shallow. May shift slightly.

Extremes of discharge.—Maximum stage recorded during year, 10.8 feet June 9 and 10 (discharge, 15,000 second-feet); minimum stage, 5.0 feet at 5 p. m. September 18 and 19 (discharge, 470 second-feet).

1915–1917: Maximum stage recorded, 12.6 feet July 11, 1915 (discharge, 21,300 second-feet); minimum stage, 4.09 feet November 15, 1914 (discharge not determined); mean discharge for the day estimated 250 second-feet.

Regulation.—Operation of power plant at Kankakee causes slight fluctuation at gage.

Accuracy.—Stage-discharge relation changed slightly during year; seriously affected by ice during winter. Rating curve used to March 12 well defined above 1,820 second-feet and fairly well defined between 1,130 and 1,820 second-feet; extended below 1,130 second-feet; curve used after March 12 well defined above and fairly well defined below 1,820 second-feet. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records good for medium and high stages and fair for low stages during open-water periods; winter records poor.

The following discharge measurement was made by H. C. Beckman:
August 10, 1917: Gage height, 6.03 feet; discharge, 1,840 second-feet.

Daily discharge, in second-feet, of Kankakee River at Custer Park, Ill., for the year ending Sept. 30, 1917.

DES PLAINES RIVER AT LEMONT, ILL.

LOCATION.—In sec. 20, T. 37 N., R. 11 E., at concrete highway bridge at Stephens Street, about a quarter of a mile north of main section of Lemont, Cook County; 8 miles above junction of Des Plaines River and Chicago Drainage Canal.

DRAINAGE AREA.—705 square miles.

RECORDS AVAILABLE.—November 4, 1914, to September 30, 1917.

GAGE.—Enamel staff gage attached to bridge; read by William Weck, jr.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge or by wading below dam.

CHANNEL AND CONTROL.—A concrete dam forming a new control and changing the former stage-discharge relation was built across the channel about 500 feet below the gage August 20, 1916; permanent.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 5.6 feet at 8 a.m. March 19 (discharge, 2,960 second-feet); minimum stage, 2.48 feet October 8, 10, 11, and 16, and September 5 (discharge, 9 second-feet).

1915–1917: Maximum stage recorded, 6.1 feet January 23, 1916 (discharge not determined because of backwater from ice); maximum open-water stage recorded, 5.9 feet June 10, 1916 (discharge, 3,380 second-feet); minimum discharge, 3.9 second-feet (measured by current meter) November 26, 1914.

ACCURACY.—Stage-discharge relation permanent; affected by ice during a short period in February. Rating curve well defined between 120 and 2,220 second-feet. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records good except those for very low stages, which are fair.

Discharge measurements of Des Plaines River at Lemont, Ill., during the year ending Sept. 30, 1917.

DES PLAINES RIVER AT JOLIET, ILL.

Location.—In NE. ¼ sec. 9, T. 35 N., R. 10 E., at Jackson Street Bridge, Joliet, Will County, about 1,200 feet upstream from Cass Street Bridge.

Drainage area.—Not measured.

Records available.—December 3, 1914, to September 30, 1917; on original chain gage September 5 to December 19, 1914.

Gage.—Gurley seven-day water-stage recorder, installed December 3, 1914. Chain gage attached to upstream side of bridge at Cass Street read from September 5 to December 19, 1914.

Discharge measurements.—Made from upstream side of Cass Street Bridge.

Channel and control.—Channel excavated in solid rock, with a concrete wall on either side; probably permanent.

Extremes of discharge.—Maximum mean daily discharge during days of record for the year, 10,600 second-feet July 24; minimum daily discharge, 6,340 second-feet January 1.

1914–1917: Maximum daily discharge during days of record, 13,200 second-feet June 10, 1916; minimum daily discharge, 5,420 second-feet, April 25, 1915.

Diversions.—Water is diverted to the Illinois & Michigan Canal at dam No. 1, about 100 feet above the gage.

Regulation.—Flow past the gage is largely regulated by the operation of the power plant of the sanitary district of Chicago at Lockport, which utilizes the flow of the Chicago Drainage Canal and, to a lesser extent, by the operation of the Economy Light & Power Co.'s plant, about 100 feet above gage.

Accuracy.—Stage-discharge relation permanent; not affected by ice. Rating curve well defined. Operation of the water-stage recorder satisfactory except for periods indicated in footnote to daily-discharge table. Daily discharge ascertained by use of discharge integrator. Records excellent.

Discharge measurements of Des Plaines River at Joliet, Ill., during the year ending Sept. 30, 1917.

[Made by H. C. Beckman.]

Date.	Gage height.	Discharge.

a No record.
b Discharge partly estimated because of incomplete gage record.

NOTE.—Daily discharge in the above table does not include the flow in the Illinois & Michigan Canal (see "Diversions" in the station description). No gage height record Oct. 20, Jan. 14-16, Feb. 5, 6, May 21-25, Aug. 4-6 and 29-31; discharge estimated.

Monthly discharge in second-feet, of Des Plaines River at Joliet, Ill., for the year ending Sept. 30, 1917.

Month.	Maximum.	Minimum.	Mean.
October	8,340	6,650	7,560
November	8,980	7,020	8,190
January	8,840	6,340	8,160
February	9,080	6,920	8,040
March 1-23	10,000	7,620	8,590
April	8,800	7,500	8,090
June	9,900	8,060	9,200
July	10,600	8,740	9,670
August	9,840	8,940	9,210

NOTE.—Discharge in the above table does not include flow of the Illinois & Michigan Canal, which diverts water around the gage. See "Diversions" in station description and measurement of flow in the canal made July 12.

FOX RIVER AT ALGONQUIN, ILL.

Location.—In NW. ¼ sec. 34, T. 43 N., R. 8 E. third principal meridian, at Chicago Street Bridge in Algonquin, McHenry County, about 100 feet above Public Service Co.'s dam and 500 feet above Crystal Lake outlet.

Records available.—October 1, 1915, to September 30, 1917.

Drainage area.—1,340 square miles (measured on map issued by U. S. Geological Survey; scale, 1 to 500,000).

Gage.—Enamel staff gage attached to concrete abutment of bridge; read by Edward Pedersen.

Channel and control.—Control is a concrete dam about 100 feet below gage; appears to be cracking and may settle.

Discharge measurements.—Made from upstream side of bridge or by wading below dam.

Extremes of discharge.—Maximum stage recorded during year, 2.8 feet at 7 a. m. and 6 p. m. March 28 (discharge, 2,260 second-feet); minimum stage, 1.10 feet September 7 and 8 (discharge, 279 second-feet).

1916–17: Maximum stage recorded, 5.3 feet at 6 p. m., March 31, 1916 (discharge, 7,120 second-feet); minimum stage, 0.98 foot August 7 and 8, 1916 (discharge, 209 second-feet).

Diversions.—Water is diverted to operate grist mill at dam, which is run on average of about 4 hours a day, except Sundays, from September to March, inclusive, and one day a week during rest of year. If total used for each day were uniformly distributed it would probably average less than 5 second-feet and never exceed 8 second-feet.

Accuracy.—Stage-discharge relation permanent; not affected by ice. Rating curve fairly well defined. Gage read to hundredths twice daily As storage pond is large the small amount of water used by grist mill does not noticeably affect the gage heights. Daily discharge ascertained by applying mean daily gage height to rating table. Records good.

Discharge measurements of Fox River at Algonquin, Ill., during the years ending Sept. 30, 1916–1917.

29	....do	1.88	[b] 963	28	....do	1.17	331

[a] Measurement made at C. & N. W. Ry. bridge 1.000 feet below gage; poor measuring section.

[b] Discharge supercedes that published in Water-Supply Paper No. 435. Vertical-velocity curves obtained in 1915 and 1918 indicate that a coefficient of 0.97 should have been applied to the mean of the velocities at 0.2 and 0.8 of the depth in order to obtain mean velocity. The coefficient had not been applied to discharge previously published for this measurement.

Daily discharge, in second-feet, of Fox River at Algonquin, Ill., for the years ending Sept. 30, 1916 and 1917.

FOX RIVER AT WEDRON, ILL.

LOCATION.—In sec. 9, T. 34 N., R. 4 E., at highway bridge at Wedron, La Salle County, about 1,000 feet above Buck Creek.

DRAINAGE AREA.—2,500 square miles.

RECORDS AVAILABLE.—November 5, 1914, to September 30, 1917.

GAGE.—Chain gage attached to bridge; read by Nels Mathias.

DISCHARGE MEASUREMENTS.—Made from upstream side of bridge.

CHANNEL AND CONTROL.—Bed of river at measuring section is soft and probably shifts. Control about 1,000 feet downstream composed of coarse gravel and large boulders; seldom shifts.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 11.6 feet at 4 p. m. March 14 (discharge, 10,200 second-feet); minimum stage, 5.90 feet at 4 p. m. September 4 (discharge 297 second-feet).

1915–1917: Maximum stage recorded, 15.4 feet March 14, 1916 (discharge not determined because of backwater from ice); maximum open-water stage recorded, 13.8 feet March 29, 1916 (discharge, 16,700 second-feet); minimum stage, 5.62 feet November 20, 1914 (discharge, 105 second-feet, by current-meter measurement).

REGULATION.—Moderate diurnal fluctuation is caused by operation of power plants at and above Montgomery.

ICE.—Stage-discharge relation seriously affected by ice.

ACCURACY.—Stage-discharge relation changed slightly by high water in March. Rating curve used to March 10 well defined between 275 and 11,300 second-feet; curve used after that date well defined between 1,130 and 11,300 second-feet, and fairly well defined beyond these limits. Gage read to hundredths twice daily. Diurnal fluctuation only moderate. Daily discharge ascertained by applying mean daily gage heights to rating tables. Results good for medium and high stages, fair for very low stages, and poor for periods of ice effect.

The following discharge measurement was made by H. C. Beckman:

August 9, 1917: Gage height, 6.52 feet; discharge, 743 second-feet.

Daily discharge, in second-feet, of Fox River at Wedron, Ill., for the year ending Sept 30, 1917.

VERMILION RIVER NEAR STREATOR, ILL.

LOCATION.—In sec. 1, T. 30 N., R. 3 E. third principal meridian, at highway bridge known as Bridge No. 3, about 1½ miles south of Streator, La Salle County, and 100 feet below Santa Fe Railway bridge.

DRAINAGE AREA.—1,080 square miles.

RECORDS AVAILABLE.—July 27, 1914, to September 30, 1917.

GAGE.—Chain gage attached to highway bridge; read by Mark Morse.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge or by wading.

CHANNEL AND CONTROL.—Gravel and rocks; probably permanent.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 11.8 feet at 4 p. m. June 6 (discharge, 5,750 second-feet); minimum stage, 0.52 foot at 9.30 a. m., October 1 (discharge, 1.3 second-feet).

1914–1917: Maximum stage recorded, 22.4 feet January 21, 1916 (discharge, estimated from extension of rating curve, 16,000 second-feet); minimum stage 0.45 foot August 16 and 17, 1914 (discharge, 0.7 second-foot).

ACCURACY.—Stage-discharge relation permanent; seriously affected by ice during winter. Rating curve well defined between 300 and 2,500 second-feet, and fairly well defined between 10 and 300 second-feet and between 2,500 and 12,000 second-feet. Gage read to hundredths once daily. Daily discharge ascertained by applying daily gage height to rating table. Records good for open-water periods, except for extremely low stages and for a period just before or after May 13, when the gage was probably read 1.0 foot in error; poor for period of ice effect.

Discharge measurements of Vermilion River near Streator, Ill., during the year ending Sept. 30, 1917.

SPOON RIVER AT SEVILLE, ILL.

Location.—In sec. 24, T. 6 N., R. 1 E. fourth principal meridian, at Toledo, Peoria & Western Railway bridge about a quarter of a mile east of railway station at Seville, Fulton County.

Drainage area.—1,600 square miles.

Records available.—July 24, 1914, to September 30, 1917.

Gage.—Chain gage attached to bridge; read to hundredths once daily by C. D. Bartlett. Elevation of zero gage above sea level, 467.78 feet.

Discharge measurements.—Made from downstream side of bridge; low water measurements are made by wading below dam at railroad station.

Channel and control.—Control is a loose rock dam, about 2 miles downstream from gage, used to create a reservoir for the pumping station of the Toledo, Peoria & Western Railway.

Extremes of stage.—Maximum stage recorded during year, 20.4 feet at 7 a. m. June 15; minimum stage, 2.10 feet at 7 a. m. October 11.

1914–1917: Maximum stage recorded, 26.0 feet January 23, 1916; minimum stage, 1.35 feet July 31, August 28 and 29, 1914.

Ice.—Stage-discharge relation affected by ice during winter.

Data inadequate for determination of discharge.

Discharge measurements of Spoon River at Seville, Ill., during the year ending Sept. 30, 1917.

NOTE.—Stage-discharge relation probably affected by ice about Dec. 11 to Mar. 11.

SANGAMON RIVER AT MONTICELLO, ILL.

LOCATION.—In sec. 12, T. 18 N., R. 5 E. third principal meridian, at Illinois Central Railroad bridge about half a mile west of Monticello, Piatt County.

DRAINAGE AREA.—550 square miles.

RECORDS AVAILABLE.—February 4, 1908, to December 31, 1912; June 23, 1914, to September 30, 1917.

GAGE.—Chain gage attached to downstream side of bridge; read by David Coay.

DISCHARGE MEASUREMENTS.—Made by wading or from downstream side of bridge and wooden trestle approach.

CHANNEL AND CONTROL.—Measuring section is at a pool; control consists of fine gravel; likely to shift.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 12.0 feet at 5 p. m. June 9 (discharge, 2,530 second-feet); minimum stage, 1.7 feet, October 9–11, 14, and 16–17 (discharge, 8 second-feet).

Maximum stage recorded during periods of records, 15.2 feet May 14, 1908 (discharge, 9,280 second-feet); maximum stage during flood of March to April, 1913, 17.7 feet March 25 (discharge not known); minimum stage recorded during periods of records, 1.5 feet July 31, August 1 and 3, 1914 (discharge, 1 second-foot).

ICE.—Stage-discharge relation seriously affected by ice.

ACCURACY.—Stage-discharge relation changed slightly several times during year. Rating curve used from March 16 to August 4 fairly well defined above 51 second-feet; curves for remainder of year fairly well defined above 5 second-feet. Gage read to quarter-tenths once a day. Daily discharge ascertained by applying daily gage height to rating table. Open-water records good; winter records poor.

Discharge measurements of Sangamon River at Monticello, Ill., during the year ending Sept. 30, 1917.

SANGAMON RIVER AT RIVERTON, ILL.

Location.—In southeast corner of SW. ¼ sec. 9, T. 16 N., R. 4 W. third principal meridian, at Wabash Railroad bridge about a quarter of a mile west of Riverton, Sangamon County, and 2½ miles below mouth of South Fork.

Drainage area.—2,560 square miles.

Records available.—February 13, 1908, to December 31, 1912; August 7, 1914, to September 30, 1917.

Gage.—Chain gage attached to bridge; read by J. J. Washburn.

Discharge measurements.—Made from downstream side of bridge or by wading.

Channel and control.—Measuring section is at a pool; control consists of fine gravel and shifts slightly.

Extremes of discharge.—Maximum stage recorded during year, 27.4 feet at 4.30 p. m. June 7 (discharge, 19,900 second-feet); minimum stage, 7.43 feet at 8 a. m. November 21 (discharge, 37 second-feet).

1908–1912; 1914–1917: Maximum stage recorded, 27.8 feet February 3, 1916 (discharge, 20,800 second-feet); high water of 1883 reached a height of about 32 feet on the present gage, and that of 1875 is said to have been one-half foot lower (discharge not estimated); minimum stage recorded, 6.9 feet October 3–15, 1915 (discharge, 3 second-feet).

Ice.—Stage-discharge relation seriously affected by ice.

Accuracy.—Stage-discharge relation changed slightly during March. Rating curves used before and after the change, well defined below and fairly well defined above 4,350 second-feet. Gage read to hundredths once daily. Daily discharge ascertained by applying daily gage height to rating table. Records good for periods for which daily discharge has been ascertained; fair for October; poor for winter.

Discharge measurements of Sangamon River at Riverton, Ill., during the year ending Sept. 30, 1917.

NOTE.—Discharge, Oct. 1 to Nov. 3, estimated because of no gage-height record, from records of discharge of Sangamon River at Monticello and at Oakford; also Dec. 11 to Feb. 23, because of ice, from gage heights, observer's notes, and weather records. Braced figures show mean discharge for periods indicated.

Monthly discharge of Sangamon River at Riverton, Ill., for the year ending Sept. 30, 1917.

SANGAMON RIVER NEAR OAKFORD, ILL.

LOCATION.—In sec. 6, T. 19 N., R. 7 W. third principal meridian, at highway bridge 3 miles northeast of Oakford, Menard County, 2½ miles above Chicago, Peoria & St. Louis Railway bridge, and 1½ miles above mouth of Crane Creek.

DRAINAGE AREA.—5,000 square miles.

RECORDS AVAILABLE.—October 26, 1909, to June 30, 1911; December 10, 1911, to March 31, 1912; August 25, 1914, to September 30, 1917.

GAGE.—Chain gage attached to bridge; read by R. W. Schnell.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge.

CHANNEL AND CONTROL.—Bed composed of sand and fine gravel; shifting. The river for some distance above and below station has been dredged and straightened, thus increasing the slope considerably and disturbing the regimen of flow.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 19.9 feet June 8 and 9 (discharge, determined from extension of rating curve, 33,300 second-feet); minimum stage, 0.68 foot October 10–18 (discharge, 135 second-feet).

1909–1912, 1914–1917: Maximum discharge June 8, 9, 1917; minimum discharge, 85 second-feet, August 30, 31, November 27, and December 2, 1914.

ICE.—Stage-discharge relation seriously affected by ice.

ACCURACY.—Stage-discharge relation not permanent. Rating curve used to March 31, 1916, fairly well defined between 310 and 17,500 second-feet; curves used after that date fairly well defined between 170 and 17,500 second-feet; extended above 17,500 second-feet. Gage read to tenths once daily till December 31, 1914, and to hundredths once or twice daily afterwards. Gage reading for March to September, 1916, somewhat unreliable. Daily discharge ascertained by applying daily gage height to rating table. Open-water records good for medium stages, and fair for low and very high stages; winter records poor.

Discharge measurements of Sangamon River near Oakford, Ill., during the year ending Sept. 30, 1917.

NOTE.—Discharge interpolated for about one-third the days in 1914 and June 11–15, 1917; ascertained from estimated gage heights June 18–26, 1917; estimated, because of ice, from gage heights, observer's notes, and weather records, for Dec. 16–31, 1914, Dec. 16–31, 1915, and Dec. 7, 1916 to Feb. 20, 1917.
Gage-height record March to September, 1916, rather unreliable.

Monthly discharge of Sangamon River near Oakford, Ill., for the years ending Sept. 30, 1914–1917.

SOUTH FORK OF SANGAMON RIVER NEAR TAYLORVILLE, ILL.

Location.—In sec. 8, T. 12 N., R. 2 W., at Wabash Railroad bridge about 3½ miles southwest of Taylorville, Christian County, and about a quarter of a mile upstream from highway bridge known as Half Acre Bridge.

Drainage area.—427 square miles.

Records available.—February 11, 1908, to December 31, 1912; August 8, 1914, to May 17, 1917, when station was discontinued.

Gage.—Chain gage attached to bridge; read by Louis Seelbach. On September 2, 1909, gage datum was lowered 2 feet. The gage heights to August 10, 1909, refer to old datum; those from August 11 to September 1, 1909, are of no value because of backwater from a construction dam built and used during that period. Gage heights from September 2, 1909, to December 31, 1912, refer to new datum. On August 8, 1914, the datum was changed by an unknown amount, all bench marks being destroyed during construction of a new concrete steel-plate girder bridge. Gage heights subsequent to August 8, 1914, refer to the datum used in reestablishing the gage on that date.

Discharge measurements.—Made from downstream side of bridge or by wading below gage.

Channel and control.—In August, 1909, a drainage ditch was dug along the river in the vicinity of the station, which straightened the course of the stream but coincided with the original channel at the gaging section. Though the cross section of the channel at the measuring section was not changed, the stage-discharge relation was considerably affected by the change in slope. Subsequent to 1912 a new bridge was built, and since then the stage-discharge relation has again changed. Measuring section is in a pool; control likely to shift.

Extremes of discharge.—1914–1917: Maximum stage recorded, 16.1 feet at 1 p. m. January 31, 1916 (discharge, 9,660 second-feet); minimum stage, 0.51 foot August 10 and 11 and September 29, 1914 (discharge, 0.6 second-foot).

Maximum discharge during periods of records same as for 1914–1917.

ICE.—Stage-discharge relation seriously affected by ice.

ACCURACY.—Stage-discharge relation changed several times from 1914 to 1917; affected by ice and by backwater from brush during spring of 1917. Rating curves used from February 1, 1915, to March 31, 1917, fairly well defined between 264 and 2,520 second-feet; rating curves for other periods poorly defined. Gage read to hundredths once daily. Daily discharge ascertained by applying daily gage height to rating table. Records fair for medium and high stages during open-water periods of 1915 and 1916; poor for remainder of time.

Discharge measurements of South Fork of Sangamon River near Taylorville, Ill., during the year ending Sept. 30, 1917.

SOUTH FORK OF SANGAMON RIVER AT POWER PLANT NEAR TAYLORVILLE, ILL.

LOCATION.—In sec. 14, T. 13 N., R. 3 W., at Chicago & Illinois Midland Railroad bridge about 6 miles northwest of Taylorville, Christian County, about 500 feet east of power plant of Central Illinois Public Service Co., 5 miles below mouth of Bear Creek, and 8 miles below station formerly maintained at Wabash Railroad bridge.

DRAINAGE AREA.—510 square miles (measured on map issued by U. S. Geological Survey, scale, 1 to 500,000).

RECORDS AVAILABLE.—May 18 to September 30, 1917.

AGE.—Chain gage attached to bridge; read by R. T. Teaney.

DISCHARGE MEASUREMENTS.—Made from upstream side of bridge or by wading.

CHANNEL AND CONTROL.—Soft mud; likely to shift.

EXTREMES OF DISCHARGE.—Maximum stage recorded during period of records, 26.6 feet June 6 (discharge, 10,400 second-feet); minimum stage, 3.68 feet at 9 a. m. August 21 (discharge, 3.8 second-feet).

A stage of about 27.3 feet on the present gage is said to have been reached January 31, 1916 (discharge, 11,300 second-feet).

DIVERSIONS.—An average of about a half second-foot of water is used for boiler-feed and other purposes at the power plant.

ACCURACY.—Stage-discharge relation probably permanent during period of records. Rating curve fairly well defined above 25 second-feet. Gage read to hundredths twice a day. Daily discharge ascertained by applying daily gage height to rating table. Records good except those for extremely low stages, which are fair.

Discharge measurements of South Fork of Sangamon River at power plant near Taylorville, Ill., during the year ending Sept. 30, 1917.

KASKASKIA RIVER AT VANDALIA, ILL.

LOCATION.—In sec. 16, T. 6 N., R. 1 E. third principal meridian, at highway bridge at east end of Main Street, Vandalia, Fayette County, about 3½ miles above Hickory Creek.

DRAINAGE AREA.—1,980 square miles.

RECORDS AVAILABLE.—February 26, 1908, to December 31, 1912; August 11, 1914, to September 30, 1917.

GAGE.—Chain gage attached to bridge; read by Wilson Haley.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge or by wading.

CHANNEL AND CONTROL.—Measuring section is at a pool; may shift.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 23.0 feet at 9 p. m. June 6 (discharge, 16,400 second-feet); minimum stage, 0.52 foot October 14 and November 16 to 19 (discharge, 19 second-feet).

1908–1912 and 1914–1917: Maximum stage recorded, 23.0 feet June 6, 1917 (discharge, 16,400 second-feet); minimum stage, 0.38 foot August 12, 1914 (discharge, 13 second-feet).

ICE.—Stage-discharge relation seriously affected by ice.

ACCURACY.—Stage-discharge relation changed during high water in June. Rating curve used till May 31 well defined between 270 and 10,800 second-feet; curve used after that date well defined between 327 and 10,800 second-feet; both curves fairly well defined beyond the limits mentioned. Gage read to hundredths once daily. Daily discharge ascertained by applying daily gage height to rating table. Open-water records good; winter records poor.

Discharge measurements of Kaskaskia River at Vandalia, Ill., during the year ending Sept. 30, 1917.

KASKASKIA RIVER AT NEW ATHENS, ILL.

Location.—In W. ½ NE. ¼ sec. 28, T. 2 S., R. 7 W. third principal meridian, at Illinois Central Railroad bridge about 600 feet north of railroad station at New Athens, St. Clair County, about a mile below mouth of Silver Creek and 3 miles above mouth of Lively Creek.

Drainage area.—5,220 square miles.

Records available.—January 23, 1907, to December 31, 1912; June 22, 1914, to September 30, 1917. Gage height of river was taken on Wednesday and Thursday mornings from January 23, 1907, to October 28, 1909, by C. J. von Roth Roffy for the New Athens Journal, and by whom they were published. Record authentic. Gage heights have been reduced to the present datum; maximum error probably not more than 0.4 foot, decreasing with increase of stage.

Gage.—Chain gage attached to bridge; read by Henry Hoffman.

Discharge measurements.—Made from downstream side of bridge to which gage is attached or from highway bridge about 500 feet downstream.

Channel and control.—Sand and gravel; may shift.

Extremes of discharge.—Maximum stage recorded during year, 26.1 feet June 14 (discharge, 25,700 second-feet); maximum discharge, 26,100 second-feet, June 13; flow for both these days affected by backwater from Mississippi River; minimum stage recorded, 2.43 feet at noon October 11 (discharge, 142 second-feet).

Maximum stage recorded during periods of records, 35.7 feet August 26, 1915 (discharge, 63,100 second-feet); minimum stage, 2.08 feet August 10, 1914 (discharge, 102-second-feet).

Ice.—Stage-discharge relation affected by ice.

Accuracy.—Stage-discharge relation changed slightly during year; affected by backwater from Mississippi River when height on gage of United States Weather Bureau at Chester, Ill., is above about 14.0 feet, and by ice during parts of winter. Rating curves used during periods of no backwater from the Mississippi fairly well defined. Gage read to hundredths once daily. Daily discharge for periods of no backwater ascertained by applying daily gage height to rating tables; for periods of backwater determined from daily gage heights at New Athens and Chester by slope method described in Water Supply Paper 345, page 53. Records fair for period of backwater effect, poor for periods of ice effect, and good for rest of year.

Discharge measurements of Kaskaskia River at New Athens, Ill., during the year ending Sept. 30, 1917.

BIG MUDDY RIVER AT PLUMFIELD, ILL.

LOCATION.—In W. ½ sec. 20, T. 7 S., R. 2 E., at highway bridge at Plumfield, Franklin County, about 6 miles west of West Frankfort, 11½ miles below mouth of Middle Fork, and 2 miles below station formerly maintained at Chicago, Burlington & Quincy Railroad bridge.

DRAINAGE AREA.—753 square miles.

RECORDS AVAILABLE.—August 18, 1914, to September 30, 1917; June 16, 1908, to September 30, 1912, and November 1, to December 31, 1912, maintained at the Chicago, Burlington & Quincy Railroad bridge.

GAGE.—Chain gage attached to bridge; read by Louis Robertson.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge or by wading.

CHANNEL AND CONTROL.—Probably permanent; low-water control is about a quarter of a mile below gage. Point of zero flow is at a stage of about 0.6 foot.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 24.7 feet at 5 p.m. January 8 (discharge, 9,770 second-feet); minimum stage, 0.84 foot at 6 p.m. October 14 (discharge, 3.4 second-feet).

1914–1917: Maximum stage recorded, 30.2 feet February 1, 1916 (discharge, 16,300 second-feet); minimum stage, August 18–26, 1914, when there was no flow past the gage.

ICE.—Stage-discharge relation seriously affected by ice.

ACCURACY.—Stage-discharge relation probably permanent during period of records except as affected by ice during parts of winters. Rating curve fairly-well defined between 43 and 13,500 second-feet. Gage read to hundredths twice daily to May 10, 1917, and once daily afterwards. Daily discharge ascertained by applying daily gage height to rating table. Records good except those for extremely low and high stages, which are fair; poor for periods of ice effect.

Discharge measurements of Big Muddy River at Plumfield, Ill., during the year ending Sept. 30, 1917.

BIG MUDDY RIVER AT MURPHYSBORO, ILL.

LOCATION.—In SW. ¼ sec. 8, T. 9 S., R. 2 W., at lower highway bridge, South Twentieth Street, about a quarter of a mile below mouth of Louis Creek at Mobile & Ohio Railway bridge.

RECORDS AVAILABLE.—December 6, 1916, to September 30, 1917.

DRAINAGE AREA.—2,170 square miles (measured on map issued by U. S. Geological Survey; scale, 1 to 500,000).

GAGE.—Chain gage attached to bridge; read by G. A. Johnson until May 21 and by E. B. Jacobs afterward.

CHANNEL AND CONTROL.—Heavy clay; may shift.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge or by wading.

EXTREMES OF DISCHARGE.—Maximum stage recorded during period of records, 33.3 feet at noon January 10 (discharge, 15,600 second-feet); minimum stage (interpolated), 2.32 feet September 30 (discharge, 29 second-feet).

About February 2, 1916, the river reached a height of 39.6 feet—the highest known stage—on the present gage (discharge, ascertained from extension of rating curve, 28,000 second-feet).

ICE.—Stage-discharge relation seriously affected by ice.

ACCURACY.—Stage-discharge relation changed slightly during high water in January; affected by ice during a period in February, and by backwater from Mississippi River when height on gage of U. S. Weather Bureau at Chester, Ill., is above about 10.0 feet. Rating curves well defined between 435 and 9,000 second-feet, and fairly well defined between 45 and 435 second-feet and between 9,000 and 18,200 second-feet. Gage read to hundredths once daily. Daily discharge during periods of no backwater ascertained by applying daily gage height to rating table; not determined for periods of backwater. Records good except those for very high and low stages, which are fair; poor for period of ice effect.

Discharge measurements of Big Muddy River at Murphysboro, Ill., during the year ending Sept. 30, 1917.

FLOOD ON CEDAR RIVER, IOWA, MARCH 23-29, 1917.

The flood on Cedar River in March, 1917, was the highest since that of March, 1906, which exceeded it by about 1 foot. A flood in the fifties exceeded it by about 3 feet. A reconnaissance of the flood situation on Cedar River in the vicinity of Cedar Falls was made March 28, 1917. Information regarding conditions on the main stream was obtained at Cedar Falls, Waterloo, and Cedar Rapids; that concerning Shellrock River was obtained at Shellrock.

The drainage area of Cedar River at Janesville is 1,660 square miles. A few miles below Janesville the Cedar is joined by Shellrock River, whose drainage area comprises 2,690 square miles. Of this area the West Fork, which unites with the Shellrock a few miles above its junction with Cedar River, drains 965 square miles. Beaver River, draining 380 square miles, enters Cedar River between the mouth of Shellrock River and Cedar Falls. The drainage area of Cedar River above Cedar Falls is therefore about 4,730 square miles, and the run-off from 65 per cent of this area is discharged into Cedar River between Janesville and Cedar Falls.

The flood of March, 1917, was due to a small amount of precipitation accompanied by high temperature that caused rapid melting of the snow on the drainage basin. At Charles City, near the eastern border of the drainage basin above Cedar Falls, the temperature rose above freezing March 21, reached 48° March 22, 58° March 23, and 42° March 24. On March 23 there was a rainfall of 0.42 inch.

As nearly as could be determined, the peaks of the March flood on the tributaries entering Cedar River between Janesville and Cedar Rapids occurred at the same time and each was as high as or higher than any that has occurred within the last ten years. The crest of the flood on Cedar River passed Waverly at 3 a. m., Cedar Falls at 8 a. m., and Waterloo about 4 p. m. March 24, Cedar Rapids about 6 p. m. March 26, and Wapello about 3 a. m. March 30.

A current-meter measurement of the flow at Cedar Rapids March 27 at a stage of 15.4 feet on the gage at that place showed a discharge of 44,900 second-feet. The discharge corresponding to the crest of the flood at that place—17.2 feet—was 54,000 second-feet.

The total damage to property from the headwaters of Cedar River to its mouth is estimated at not over $50,000. All streams above Cedar Falls were covered with ice about 24 inches thick until March 22. Small bridges and dams on tributary streams were damaged when the ice broke up, but aside from knocking out a few timbers in the bulkhead of the Nashua dam, the ice did no serious damage at that place. An ice gorge on Cedar River between Nashua and Waverly held the water back for several hours March 23, and when this gorge was dynamited about 9 p. m. March 23, there was a sudden rise of about 3 feet in the stage at the dam at Waverly. There was no damage to property at Waverly, but considerable inconvenience was caused when the power plant had to shut down for a short time. About two-thirds of the apron of the timber dam on Shellrock River at Shellrock was carried out by ice, the damage being about $300. A steel truss bridge at Greene, and three small pile bridges on West Fork, were taken out by the ice. The cost of replacing the steel bridge is estimated at $3,000, and the pile bridges $6,000.

The flood did most damage in the vicinity of Cedar Falls. The total damage to property was estimated by the city engineer at not more than $30,000, exclusive of small losses of private individuals. Of this sum the damage to property which would have to be replaced by the city is estimated at $15,000. One pile bridge of the Illinois Central Railroad was carried out and roadbed washed away in several places, the damage being estimated at $3,000. Damage to the Rock Island Railroad was estimated at $2,500—the cost of replacing a fill about three-fourths of a mile long, between Cedar Falls and Waterloo.

At Waterloo there was no material damage to property, but considerable inconvenience was caused by flooding of basements of residences and business houses. Residents had to move out from six blocks of well-settled residence districts. Flooding of the business district of East Waterloo was prevented by increasing the height of the levee.

There was no damage of consequence to property in Cedar Rapids or below that place.

STREAM-GAGING STATIONS

AND

PUBLICATIONS RELATING TO WATER RESOURCES

PART V. HUDSON BAY AND UPPER MISSISSIPPI RIVER DRAINAGE BASINS

STREAM-GAGING STATIONS AND PUBLICATIONS RELATING TO WATER RESOURCES.

INTRODUCTION.

Investigation of water resources by the United States Geological Survey has consisted in large part of measurements of the volume of flow of streams and studies of the conditions affecting that flow, but it has comprised also investigation of such closely allied subjects as irrigation, water storage, water powers, underground waters, and quality of waters. Most of the results of these investigations have been published in the series of water-supply papers, but some have appeared in the bulletins, monographs, professional papers, and annual reports.

The results of stream-flow measurements are now published annually in 12 parts, each part covering an area whose boundaries coincide with natural drainage features as indicated below:

Part I. North Atlantic slope basins.
II. South Atlantic slope and eastern Gulf of Mexico basins.
III. Ohio River basin.
IV. St. Lawrence River basin.
V. Upper Mississippi River and Hudson Bay basin.
VI. Missouri River basin.
VII. Lower Mississippi River basin.
VIII. Western Gulf of Mexico basins.
IX. Colorado River basin.
X. Great basin.
XI. Pacific Slope basins in California.
XII. North Pacific slope basins, published in three volumes:
A, Pacific slope basins in Washington and upper Columbia River basin.
B, Snake River basin.
C, Lower Columbia River basin and Pacific slope basins in Oregon.

HOW GOVERNMENT REPORTS MAY BE OBTAINED OR CONSULTED.

Water-supply papers and other publications of the United States Geological Survey containing data in regard to the water resources of the United States may be obtained or consulted as indicated below:

1. Copies may be obtained free of charge by applying to the Director of the Geological Survey, Washington, D. C. The edition printed for free distribution is, however, small and is soon exhausted.
2. Copies may be purchased at nominal cost from the Superintendent of Documents, Government Printing Office, Washington, D. C., who will on application furnish lists giving prices.
3. Sets of the reports may be consulted in the libraries of the principal cities in the United States.

4. Complete sets are available for consultation in the local offices of the water-resources branch of the Geological Survey, as follows:

Boston, Mass., 2500 Customhouse.
Albany, N. Y., 704 Journal Building.
Atlanta, Ga., Post Office Building.
Madison, Wis., care of Railroad Commission of Wisconsin.
Helena, Mont., Montana National Bank Building.
Topeka, Kans., 25 Federal Building.
Austin, Tex., Capitol Building.
Denver, Colo., 403 New Post Office Building.
Salt Lake City, Utah, 421 Federal Building.
Boise, Idaho, 615 Idaho Building.
Portland, Oreg., 606 Post Office Building.
Tacoma, Wash., 406 Federal Building.
San Fancisco, Calif., 328 Customhouse.
Los Angeles, Calif., 619 Federal Building.
Tucson, Ariz., University of Arizona.
Honolulu, Hawaii, 14 Capitol Building.

A list of the Geological Survey's publications may be obtained by applying to the Director of the United States Geological Survey, Washington, D. C.

STREAM-FLOW REPORTS.

Stream-flow records have been obtained at more than 4,240 points in the United States, and the data obtained have been published in the reports tabulated below:

Stream-flow data in reports of the United States Geological Survey.

[A—Annual Report; B—Bulletin; W—Water-Supply Paper.]

NOTE.—No data regarding stream flow are given in the 15th and 17th annual reports.

The records at most of the stations discussed in these reports extend over a series of years, and miscellaneous measurements at many points other than regular gaging stations have been made each year. An index of the reports containing records obtained prior to 1904 has been published in Water-Supply Paper 119.

The following table gives by years and drainage basins the numbers of the papers on surface-water supply published from 1899 to 1917. The data for any particular station will in general be found in the reports covering the years during which the station was maintained. For example, data for Machias River at Whitneyville, Me., 1903 to 1917, are published in Water-Supply Papers 97, 124, 165, 201, 241, 261, 281, 301, 321, 351, 381, 401, 431, and 451 which contain records for the New England streams from 1903 to 1917. Results of miscellaneous measurements are published by drainage basins.

In these papers and in the following lists the stations are arranged in downstream order. The main stem of any river is determined by measuring or estimating its drainage area—that is, the headwater stream having the largest drainage area is considered the continuation of the main stream, and local changes in name and lake surface are disregarded. All stations from the source to the mouth of the main stem of the river are presented first, and the tributaries in regular order from source to mouth follow, the streams in each tributary basin being listed before those of the next basin below.

In exception to this rule the records for Mississippi River are given in four parts, as indicated on page III, and the records for large lakes are taken up in order of streams around the rim of the lake.

Numbers of water-supply papers containing results of stream measurements, 1899–1917.[a]

a Rating tables and index to Water-Supply Papers 35–39 contained in Water-Supply Paper 39. Tables of monthly discharge for 1899 in Twenty-first Annual Report, Part IV.
b James River only.
c Gallatin River.
d Green and Gunnison rivers and Grand River above junction with Gunnison.
e Mohave River only.
f Kings and Kern rivers and south Pacific slope drainage basins.
g Rating tables and index to Water-Supply Papers 47–52 and data on precipitation, wells, and irrigation in California and Utah contained in Water-Supply Paper 52. Tables of monthly discharge for 1900 in Twenty-second Annual Report, Part IV.
h Wissahickon and Schuylkill rivers to James River.
i Scioto River.
j Loup and Platte rivers near Columbus, Nebr., and all tributaries below junction with Platte.
k Tributaries of Mississippi from east.
l Lake Ontario and tributaries to St. Lawrence River proper.
m Hudson Bay only.
n New England Rivers only.
o Hudson River to Delaware River, inclusive.
p Susquehanna River to Yadkin River, inclusive.
q Platte and Kansas rivers.
r Great Basin in California except Truckee and Carson river basins.
s Below junction with Gila.
t Rogue, Umpqua, and Siletz rivers only.

PART V.—HUDSON BAY AND UPPER MISSISSIPPI RIVER DRAINAGE BASINS.

PRINCIPAL STREAMS.

The Hudson Bay and upper Mississippi River basins include streams whose waters reach Hudson Bay and the Mississippi above its junction with the Ohio (except the Missouri). The principal streams flowing into Hudson Bay from the United States are St. Mary River, Red River, and Rainy River. The principal tributaries of the upper Mississippi are Crow Wing, Sauk, Crow, Rum, Minnesota, St. Croix, Chippewa, Zumbro, Black, Root, Wisconsin, Wapsipinicon, Rock, Iowa, Des Moines, Illinois, and Kaskaskia rivers. These streams drain wholly or in part the States of Illinois, Indiana, Iowa, Minnesota, Missouri, Montana, North Dakota, South Dakota, and Wisconsin.

In addition to the list of gaging stations and the annotated list of publications relating specifically to the section, these pages contain a similar list of reports that are of general interest in many sections and cover a wide range of hydrologic subjects, and also brief references to reports published by State and other organizations. (See p. xvii.)

GAGING STATIONS.

NOTE.—Dash after a date indicates that station was being maintained September 30, 1917. Period after a date indicates dicontinuance.

HUDSON BAY DRAINAGE BASIN.

St. Mary River near Babb (formerly dam site), Mont., 1902–
St. Mary River below Swiftcurrent Creek, at Babb, Mont., 1901–2; 1910–1915.
St. Mary River near Kimball, Alberta, 1902–
  Swiftcurrent Creek at Many Glacier, Mont., 1912–
  Swiftcurrent Creek at Sherburne, Mont., 1912–
  Swiftcurrent Creek near Babb (formerly Wetzel) Mont., 1902–1910.
  U. S. Reclamation Service, St. Mary canal at Hudson Bay divide near Browning, Mont., 1917–
  Kennedy Creek near Babb (formerly Wetzel), Mont., 1903–1907.
Ottertail River at German Church, near Fergus Falls, Minn., 1913–1917.
Ottertail River near Fergus Falls, Minn., 1904–1913.
Red River near Fergus Falls, Minn., 1909–10.
Red River at Fargo, N. Dak., 1901–
Red River at Grand Forks, N. Dak., 1901–
Red River at Pembina, N. Dak., 1901.
Red River at Emerson, Manitoba, 1900–1902.
  Mustinka River near Wheaton, Minn., 1916; 1917.
  Pelican River near Fergus Falls, Minn., 1909–1912.
  Sheyenne River at Haggart, N. Dak., 1902–1907.
  Wild Rice River at Twin Valley, Minn., 1909–1917.
    Devils Lake near Devils Lake, N. Dak., 1901–
  Red Lake River at Thief River Falls, Minn., 1909–

Red River tributaries—Continued.
- Red Lake River at Crookston, Minn., 1901–
  - Thief River near Thief River Falls, Minn., 1909–1917.
  - Clearwater River at Red Lake Falls, Minn., 1909–1917.
  - South Branch of Two Rivers at Hallock, Minn., 1911–1914.
- Pembina River at Necho, N. Dak., 1903–1915.
  - Roseau River at Dominion City, Canada, 1912.
  - Roseau River near Caribou, Minn., 1917.
    - West Branch of Roseau River near Malung, Minn., 1911–1914.
- Mouse River near Foxholm, N. Dak., 1904–1906.
- Mouse River at Minot, N. Dak., 1903–
  - Des Lacs River at Foxholm, N. Dak., 1904–1906.
- Rainy Lake at Rainier, Minn., 1910–1917.
- Rainy River at International Falls, Minn., 1907–1917.
- Kawishiwi River near Winton, Minn., 1905–1907; 1912–
  - Vermilion River below Lake Vermilion, near Tower, Minn., 1911–1917.
  - Little Fork at Little Fork, Minn., 1909–1917.
  - Big Fork at Big Falls, Minn., 1909–1912.
  - Big Fork at Laurel, Minn., 1909.
  - Black River near Loman, Minn., 1909.

UPPER MISSISSIPPI RIVER BASIN.

Mississippi River above Sandy River, Minn., 1895–1915.
Mississippi River near Fort Ripley, Minn., 1909–10.
Mississippi River near Sauk Rapids, Minn., 1903–1906.
Mississippi River at Elk River, Minn., 1915–
Mississippi River at Anoka, Minn., 1905–1914.
Mississippi River at St. Paul, Minn., 1873–
- Sandy River below Sandy Lake reservoir, Minn., 1893–1916.
- Pine River below Pine River reservoir, Minn., 1886–1916.
- Prairie River near Grand Rapids, Minn., 1909.
- Crow Wing River at Nimrod, Minn., 1910–1914.
- Crow Wing River at Motley, Minn., 1909; 1913–1917.
- Crow Wing River at Pillager, Minn., 1903; 1909–1913.
- Long Prairie River near Motley, Minn., 1909–1917.
- Sauk River near St. Cloud, Minn., 1909–1913.
- Elk River near Big Lake, Minn., 1911–1917.
- Crow River at Rockford, Minn., 1909–1917.
- Crow River near Dayton, Minn., 1906.
  - North Fork of Crow River near Rockford, Minn., 1909–10.
  - South Fork of Crow River near Rockford, Minn., 1909–1912.
- Rum River at Onamia, Minn., 1909–1912.
- Rum River at Cambridge, Minn., 1909–1914.
- Rum River at St. Francis, Minn., 1903.
- Rum River near Anoka, Minn., 1905–6; 1909.
- Minnesota River near Odessa, Minn., 1909–1913.
- Minnesota River near Montevideo, Minn., 1909–
- Minnesota River near Mankato, Minn., 1903–
  - Whetstone River near Big Stone, S. Dak., 1910–1912.
  - Lac qui Parle River at Lac qui Parle, Minn., 1910–1914.
  - Chippewa River near Watson, Minn., 1909–1917.
  - Redwood River near Redwood Falls, Minn., 1909–1914.
  - Cottonwood River near New Ulm, Minn., 1909–1913.
  - Blue Earth River, at Rapidan Mills, Minn., 1909–10.

Mississippi River tributaries—Continued.
- St. Croix River at Swiss, Wis., 1914–
- St. Croix River near St. Croix Falls, Wis., 1902–1905; 1910–
  - Namakagon River at Trego, Wis., 1914–
  - Yellow River at Webster, Wis., 1914.
  - Kettle River near Sandstone, Minn., 1908–1916.
  - Snake River at Mora, Minn., 1909–1913.
  - Snake River near Pine City, Minn., 1913–1917.
  - Apple River near Somerset, Wis., 1901–
  - Kinnikinnic River near River Falls, Wis., 1916–
- Cannon River at Welch, Minn., 1909–1914.
- Chippewa River at Bishops Bridge, near Winter, Wis., 1912–
- Chippewa River near Bruce, Wis., 1913–
- Chippewa River at Chippewa Falls, Wis., 1888–
- Chippewa River near Eau Claire, Wis., 1902–1909.
  - West Fork of Chippewa River near Winter, Wis., 1911–1916.
  - Flambeau River near Butternut, Wis., 1914–
  - Flambeau River near Ladysmith, Wis., 1914–
  - Flambeau River at Ladysmith, Wis., 1903–1906.
  - Jump River at Sheldon, Wis., 1915–
  - Eau Claire River near Augusta, Wis., 1914–
  - Eau Claire River near Eau Claire, Wis., 1913–14.
  - Red Cedar River near Colfax, Wis., 1914–
  - Red Cedar River at Cedar Falls, Wis., 1909–
  - Red Cedar River at Menominee, Wis., 1907–8; 1913–
- Zumbro River at Zumbro Falls, Minn., 1909–1917.
  - South Branch of Zumbro River near Zumbro Falls, Minn., 1911–1917.
- Trempealeau River at Dodge, Wis., 1913–
- Black River at Neillsville, Wis., 1905–1909; 1913–
- Black River at Melrose, Wis., 1902–3.
- La Crosse River near West Salem, Wis., 1913–
- Root River near Houston, Minn., 1909–1917.
  - North Branch of Root River near Lanesboro, Minn., 1910–1917.
- Upper Iowa River near Decorah, Iowa, 1913–14.
- Wisconsin River near Rhinelander, Wis., 1905–1915.
- Wisconsin River at Whirlpool Rapids, near Rhinelander, Wis., 1915–
- Wisconsin River at Merrill, Wis., 1902–
- Wisconsin River near Nekoosa, Wis., 1914–
- Wisconsin River near Necedah, Wis., 1902–1914.
- Wisconsin River at Muscoda, Wis., 1902–3; 1913–
  - Tomahawk River near Bradley, Wis., 1914–
  - Prairie River near Merrill, Wis., 1914–
  - Little Rib River near Wausau, Wis., 1914–1916.
  - Eau Claire River at Kelley, Wis., 1914–
  - Big Eau Pleine River near Stratford, Wis., 1914–
  - Plover River near Stevens Point, Wis., 1914–
  - Baraboo River near Baraboo, Wis., 1913–
  - Kickapoo River at Gays Mills, Wis., 1913–
- Turkey River at Garber, Iowa, 1913–1916.
- Maquoketa River above mouth of North Fork, near Maquoketa, Iowa, 1913–14.
- Maquoketa River at Manchester, Iowa, 1903.
- Maquoketa River below mouth of North Fork, near Maquoketa, Iowa, 1913–
- Wapsipinicon River at Stone City, Iowa, 1903–1914.
- Rock River at Watertown, Wis., 1914.

Mississippi River tributaries—Continued.
- Rock River at Afton, Wis., 1914–
- Rock River above mouth of Pecatonica River, at Rockton, Ill., 1903.
- Rock River below mouth of Pecatonica River, at Rockton, Ill., 1903–1909.
- Rock River at Rockford, Ill., 1914–
- Rock River near Nelson, Ill., 1906.
- Rock River at Sterling, Ill., 1905–6.
- Rock River at Lyndon, Ill., 1914–
  - Catfish River at Madison, Wis., 1902–3.
  - Lake Mendota at Madison, Wis., 1902–3.
  - Yahara River near Edgerton, Wis., 1916–17.
  - Pecatonica River at Dill, Wis., 1914–
  - Pecatonica River at Freeport, Ill., 1914–
    - Sugar River near Brodhead, Wis., 1914–
- Iowa River near Iowa Falls, Iowa, 1911–1914.
- Iowa River at Marshalltown, Iowa, 1903; 1915–
- Iowa River at Iowa City, Iowa, 1903–1906; 1913–
- Iowa River at Wapello, Iowa, 1915–
  - Cedar River near Austin, Minn., 1909–1914.
  - Cedar River at Janesville, Iowa, 1905–6; 1915–
  - Cedar River at Cedar Rapids, Iowa, 1902–
    - Shellrock River near Clarksville, Iowa, 1915–
- Skunk River at Coppock, Iowa, 1913–
- Skunk River at Augusta, Iowa, 1913; 1915–
- Des Moines River at Jackson, Minn., 1909–1913.
- Des Moines River at Fort Dodge, Iowa, 1905–6; 1911–1913.
- Des Moines River at Kalo, Iowa, 1913–
- Des Moines River at Des Moines, Iowa, 1902–3; 1905–6; 1914–
- Des Moines River at Ottumwa, Iowa, 1917–
- Des Moines River at Keosauqua, Iowa, 1903–1906; 1911–
  - Raccoon River near Des Moines, Iowa, 1902–3.
  - Raccoon River at Van Meter, Iowa, 1915–
- Illinois River near Minooka, Ill., 1902–1904.
- Illinois River near Seneca, Ill., 1902–3.
- Illinois River near Ottawa, Ill., 1902–1904.
- Illinois River near La Salle, Ill., 1902–3.
- Illinois River at Peoria, Ill., 1910–
- Illinois River near Peoria, Ill., 1903–1906.
  - Kankakee River at Davis, Ind., 1905–6.
  - Kankakee River at Momence, Ill., 1905–6; 1914–
  - Kankakee River at Custer Park, Ill., 1914–
    - Yellow River at Knox, Ind., 1905–6.
  - Des Plaines River at Riverside, Ill., 1896–1898.
  - Des Plaines River above mouth of Jackson Creek, near Channahon, Ill., 1903–1906.
  - Des Plaines River above Kankakee River, near Channahon, Ill., 1902–3.
  - Des Plaines River at Lemont, Ill., 1914–
  - Des Plaines River at Romeo, Ill., 1914.
  - Des Plaines River at Joliet, Ill., 1914–
  - Fox River at Algonquin, Ill., 1915–
  - Fox River at South Elgin, Ill., 1914–15.
  - Fox River at Aurora, Ill., 1914.
  - Fox River at Sheridan, Ill., 1905–6.
  - Fox River at Wedron, Ill., 1914–

Mississippi River tributaries—Continued.
- Illinois River tributaries—Continued.
  - Fox River at Ottawa, Ill., 1903.
  - Vermilion River near Streator, Ill., 1914–
  - Spoon River at Seville, Ill., 1914–
  - Sangamon River at Monticello, Ill., 1908–1912; 1914–
  - Sangamon River at Decatur, Ill., 1905.
  - Sangamon River at Riverton, Ill., 1908–1912; 1914–
  - Sangamon River at Springfield, Ill., 1903.
  - Sangamon River near Oakford, Ill., 1909–1912; 1914–
  - Sangamon River near Chandlerville, Ill., 1908–9.
    - South Fork of Sangamon River near Taylorville, Ill., 1908–1912; 1914–1917.
    - South Fork Sangamon River at power plant near Taylorville, Ill., 1917–
    - Salt Creek near Kenny, Ill., 1908–1912.
- Cahokia Creek at Poag, Ill., 1909–1912.
- Kaskaskia River near Arcola, Ill., 1908–1912.
- Kaskaskia River at Shelbyville, Ill., 1908–1912; 1914.
- Kaskaskia River at Vandalia, Ill., 1908–1912; 1914–
- Kaskaskia River at Carlyle, Ill., 1908–1912; 1914–15.
- Kaskaskia River at New Athens, Ill., 1907–1912; 1914–
  - Shoal Creek near Breese, Ill., 1909–1912; 1914.
  - Silver Creek near Lebanon, Ill., 1908–1912; 1914.
- Big Muddy River near Cambon, Ill., 1908–1912.
- Big Muddy River at Plumfield, Ill., 1914–
- Big Muddy River at Murphysboro, Ill., 1917–
  - Beaucoup Creek near Pinckneyville, Ill., 1908–1912; 1914.

REPORTS ON WATER RESOURCES OF THE HUDSON BAY AND UPPER MISSISSIPPI RIVER BASINS.

PUBLICATIONS OF THE UNITED STATES GEOLOGICAL SURVEY.

WATER-SUPPLY PAPERS.

Water-supply papers are distributed free by the Geological Survey as long as its stock lasts. An asterisk (*) indicates that this stock has been exhausted. Many of the papers marked in this way may, however, be purchased (at prices quoted) from the SUPERINTENDENT OF DOCUMENTS, WASHINGTON, D. C. Omission of the price indicates that the report is not obtainable from Government sources. Water-supply papers are of octavo size.

*21. Wells of northern Indiana, by Frank Leverett. 1899. 82 pp., 2 pls.

Discusses, by counties, glacial deposits and sources of well waters; many well sections.

*44. Profiles of rivers in the United States, by Henry Gannett. 1901. 100 pp., 11 pls. 15c.

Gives elevations and distances along Red River (of the North), and Minnesota, Skunk, Iowa, Des Moines, Illinois, and Rock rivers; also brief descriptions.

*57. Preliminary list of deep borings in the United States, Part I (Alabama-Montana), by N. H. Darton. 1902. 60 pp. 5c.

*61. Preliminary list of deep borings in the United States, Part II (Nebraska-Wyoming), by N. H. Darton. 1902. 67 pp. 5c.

A revised edition of Nos. 57 and 61 was published in 1905 as Water-Supply Paper 149 (q. v.).

96. Destructive floods in the United States in 1903, by E. C. Murphy. 1904. 81 pp., 13 pls. 15c.

Contains notes on early floods in Mississippi Valley.

102. Contributions to the hydrology of eastern United States, 1903; M. L. Fuller, geologist in charge. 1904. 522 pp. 30c.

Contains brief reports on wells and springs of Minnesota and Missouri.

The reports comprise tabulated well records giving information as to location, owner, depth, yield, head, etc., supplemented by notes as to elevation above sea, material penetrated, temperature, use, and quality; many miscellaneous analyses.

*103. A review of the laws forbidding pollution of inland waters in the United States, by E. B. Goodell. 1904. 120 pp.

Cites statutory restrictions of water pollution in Iowa, Illinois, North Dakota, South Dakota, and Wisconsin. Superseded by 152.

*114. Underground waters of eastern United States; M. L. Fuller, geologist in charge. 1905. 285 pp., 18 pls. 25c.

Contains brief reports as follows: Missouri, by E. M. Shepard; Iowa, by W. H. Norton; Minnesota, by C. W. Hall; Wisconsin district, by Alfred R. Schultz; Illinois, by Frank Leverett; Indiana, by Frank Leverett; each of these reports describes briefly the topography of the area, the relation of the geology to the water supplies, and gives list of pertinent publications; lists also principal mineral springs.

117. The lignite of North Dakota and its relation to irrigation, by F. A. Wilder. 1905. 59 pp., 8 pls. 10c.

Describes the thickness, extent, variations, and fuel value of the lignite and its use for pumping water, the area, soils, and lignite of the river flats, and the st.tus of irrigation in the State.

*122. Relation of the law to underground waters, by D. W. Johnson. 1905. 55 pp. 5c.

Cites legislative acts affecting underground waters in South Dakota and Wisconsin.

145. Contributions to the hydrology of eastern United States, 1905; M. L. Fuller, geologist in charge. 1905. 220 pp., 6 pls. 10c.

Contains two reports relating to areas draining to Hudson Bay or upper Mississippi River.

Water resources of Mineral Point quadrangle, Wisconsin, by U. S. Grant. Describes springs, streams, and shallow and deep wells.

Water supplies at Waterloo, Iowa, by W. H. Norton. Summarizes results of investigations to determine availability of artesian water to replace the surface supply from Cedar River; discusses necessity of test wells, supplementary supplies, artesian head, and permanency of flow.

*149. Preliminary list of deep borings in the United States, second edition, with additions, by N. H. Darton. 1905. 175 pp. 10c.

Gives by States (and within the States by counties), the location, depth, diameter, yield height of water, and other features of wells 400 feet or more in depth; includes all wells listed in Water-Supply Papers 57 and 61; mentions also principal publications relating to deep borings.

*152. A review of the laws forbidding pollution of the inland waters in the United States (second edition), by E. B. Goodell. 1905. 149 pp. 10c.

Cities statutory restrictions of water pollution in Iowa, Illinois, North Dakota, South Dakota, and Wisconsin.

*156. Water powers of northern Wisconsin, by L. S. Smith. 1906. 145 pp., 5 pls. 25c.

Describes by river systems the drainage, geology, topography, rainfall and run-off, water powers, and dams.

*162. Destructive floods in the United States in 1905, with a discussion of flood discharge and frequency and an index of flood literature, by E. C. Murphy and others. 1906. 105 pp., 4 pls. 15c.

Contains accounts of floods in southeastern Minnesota, on Devils Creek, Iowa, and in Des Moines County, Iowa; gives estimates of flood discharge and frequency on Illinois River and on Mississippi River at St. Paul.

*193. The quality of surface waters in Minnesota, by R. B. Dole and F. F. Westbrook. 1907. 171 pp., 7 pls. 25c.

Describes by river basins the topography, geology, and soils, the individual and municipal pollution of the streams, and gives notes on the municipalities; contains many analyses.

*194. Pollution of Illinois and Mississippi Rivers by Chicago sewage (a digest of the testimony taken in the case of the State of Missouri *v.* the State of Illinois and the Sanitary District of Chicago), by M. O. Leighton. 1907. 369 pp., 2 pls.

Scope indicated by amplification of title.

*195. Underground waters of Missouri, their geology and utilization, by E. M. Shepard. 1907. 224 pp., 6 pls. 30c.

Describes the topography and geology of the State, the waters of the various formations, and discusses the water supplies by districts and counties, gives statistics of city water supplies, analyses of waters, and many well records.

*227. Geology and underground waters of South Dakota, by N. H. Darton. 1909. 156 pp., 15 pls. 40c.

Describes physical features, geologic formations, water horizons, and, by counties, deep wells and well prospects; gives notes on construction and management of artesian wells.

236. The quality of surface waters in the United States: Part I, Analyses of waters east of the one hundredth meridian, by R. B. Dole. 1909. 123 pp. 10c.

Describes collection of samples, methods of examination, preparation of solutions, accuracy of estimates and expression of analytical results; gives results of analyses of waters of Mississippi, Minnesota, Chippewa, Wisconsin, Rock, Iowa, Cedar, Des Moines, Illinois, Kankakee, Fox, Sangamon, Kaskakia, and Big Muddy rivers.

239. The quality of the surface waters of Illinois, by W. D. Collins. 1910. 94 pp., 3 pls. 10c.

Discusses the natural and economic features that determine the character of the streams, describes the larger drainage basins, and the methods of collecting and analyzing the samples of water, and discusses each river in detail with reference to its source and course and the quality of water; includes short chapters on municipal supplies and industrial uses.

254. The underground waters of north-central Indiana, by S. R. Capps, with a chapter on the chemical character of the waters, by R. B. Dole. 1910. 279 pp., 7 pls. 40c.

Describes relief, drainage, vegetation, soils, and crops, industrial development, geologic formations; sources, movements, occurence, and volume of ground water; methods of well construction and lifting devices; discusses, in detail for each county, surface features and drainage, geology and ground water, city, village, and rural supplies, and gives records of wells and analyses of waters. Discusses also, under chemical character, methods of analyses and expression of results, mineral constituents, effect of the constituents on waters for domestic, industrial, and medicinal uses, methods of purification, chemical composition; many analyses and field assays.

256. Geology and underground waters of southern Minnesota, by C. W. Hall, O. E. Meinzer, and M. L. Fuller. 1911. 406 pp., 18 pls. 60c

Discusses the physiography of the State, geologic formations and their water-bearing capacity, artesian conditions, the mineral quality of the underground waters, types of wells, finishing wells in sand, drilling in quarzite, fluctuation in yield and head, "blowing" and "breathing" wells, freezing of wells, drainage by wells, hydraulic rams, and scientific prospecting for water, municipal supplies, power, storage and distribution, consumption of water, prices, sanitation. Gives by counties details concerning surface features, rocks, yield, head, and quality of water, and summaries and analyses.

293. Underground water resources of Iowa, by W. H. Norton, W. S. Hendrixson, H. E. Simpson, O. E. Meinzer, and others. 1912. 994 pp., 18 pls. 70c.

Describes the relief, drainage, temperature, and precipitation of the State and the geologic formations; discusses the geologic occurrence of ground waters, artesian phenomena and yield of artesian wells, the chemical composition of ground waters, municipal, domestic, and industrial water supplies, and mineral waters; gives details concerning topography, geology, ground waters, and city and village supplies by districts and counties.

*345. Contributions to the hydrology of the United States, 1914. N. C. Grover, chief hydraulic engineer. 1915. 225 pp., 17 pls. 30c. Contains:

(f) Gazetteer of surface waters of Iowa, by W. G. Hoyt and H. J. Ryan, pp. 169-221.

364. Water analyses from the laboratory of the United States Geological Survey, tabulated by F. W. Clarke, chief chemist. 1914. 40 pp. 5c.

Contains analyses of spring and well waters from Nashville and Macomb, Ill., and Story City, Iowa.

417. Profile surveys of rivers in Wisconsin, prepared under the direction of W. H. Herron, acting chief geographer. 1917. 16 pp., 32 pls. 45c.

Contains brief description of general features of drainage of Wisconsin and of the rivers surveyed, but consists chiefly of maps showing "not only the outlines of the river banks, the islands, the position of rapids, falls, shoals, and existing dams, and the crossings of all ferries and roads, but the contours of banks to an elevation high enough to indicate the possibilitiey of using the stream" for the development of power by low or medium heads.

ANNUAL REPORTS.

Each of the papers contained in the annual reports was also issued in separate form.

Annual reports are distributed free by the Geological Survey as long as its stocks lasts. An asterisk (*) indicates that this stock has been exhausted. Many of the papers so marked, however, may be purchased, from the SUPERINTENDENT OF DOCUMENTS, WASHINGTON, D. C.

*Sixteenth Annual Report of the United States Geological Survey, 1894–95. 4 parts.

*Pt. II. Papers of an economic character, XIX, 598 pp., 43 pls. $1.25. Contains:

The public lands and their water supply, by F. H. Newell, pp. 457-533, pls. 35 to 39. Describes general character of the public lands, the lands disposed of (railroad, grant, and swamp lands, and private miscellaneous entries), lands reserved (Indian, forest, and military reservations), the vacant lands, and the rate of disposal of vacant lands; discusses the streams, wells, and reservoirs as sources of water supply; gives details for each State.

Seventeenth Annual Report of the United States Geological Survey, 1895–96, Charles D. Walcott, Director, 1896; 3 parts in 4 vols. *Pt. II. Economic geology and hydrography, xxv, 864 pp., 113 pls. $2.35. Contains:

Preliminary report on artesian waters of a portion of the Dakotas, by N. H. Darton, pp. 603–694, pls. 69 to 107. Gives an outline of the geologic relations; describes the water horizons and the extent of the artesian water, and gives details concerning wells and prospects by counties; discusses the origin, amount, pressure, head, and composition of the artesian waters, the use of artesian water for power, and gives details concerning artesian irrigation by counties; contains also remarks on the construction and management of artesian wells.

*The water resources of Illinois, by Frank Leverett, pp. 695–849, pls. 108 to 113. Describes the physical features of the State, and the drainage basins, including Illinois, Des Plaines, Kankakee, Fox, Illinois-Vermilion, Spoon, Mackinaw, and Sangamon rivers, Macoupin Creek, Rock River, tributaries of the Mississippi in western Illinois, Kaskaskia, Big Muddy, and tributaries of the Wabash; discusses the rainfall and run-off, navigable waters and water powers, the wells supplying waters for rural districts, and artesian wells; contains tabulated artesian well data and water analyses.

Eighteenth Annual Report of the United States Geological Survey, 1896–97, 5 parts in 6 vols. *Pt. IV, Hydrography, x, 756 pp., 102 pls. $1.75. Contains:

*The water resources of Indiana and Ohio, by Frank Leverett, pp. 419–560, pls. 33 to 37. Describes the Wabash, Whitewater, Great Miami, Little Miami, Scioto, Hocking, Muskingum, and Beavers rivers, and lesser tributaries of the Ohio in Indiana and Ohio, the streams discharging into Lake Erie and Lake Michigan, and streams flowing to the upper Mississippi through the Illinois; discusses shallow and drift wells, the flowing wells, from the drift and deeper artesian wells, and gives records of wells at many of the cities; describes the mineral springs, and gives analyses of the waters; contains also tabulated lists of cities using surface waters for water works, and of cities and villages using shallow and deep-well waters; discusses the source and quality of the city and village supplies, and gives precipitation tables for various points.

MONOGRAPHS.

Monographs of quarto size. They are not distributed free, but may be obtained from the Geological Survey or from the SUPERINTENDENT OF DOCUMENTS, WASHINGTON, D. C., at the prices indicated. An asterisk (*) indicates that the Survey's stock of the paper is exhausted.

25. The glacial Lake Agassiz, by Warren Upham. 1896. 658 pp., 38 pls. $1.70.

Contains a chapter (pp. 523–582) on "Artesian and common wells of the Red River Valley," which discusses the sources of artesian water, the fresh waters in the drift sheets, the saline and alkaline waters in the Dakota sandstone, and the use of artesian water for irrigation; contains analyses of waters from wells, streams, and lakes in Red River Valley and the adjoining region; and gives notes on wells in Clay, Kittson, Marshall, Norman, Polk, Traverse, and Wilkin counties, in Minnesota; in Cass, Grand Forks, Pembina, Richland, Traill, and Walsh counties, in North Dakota; and in a part of the area covered by Lake Agassiz, in Manitoba. The monograph includes numerous maps relating to the Pleistocene geology of the region and a map (Pl. XXXVII) showing the distribution and depths of artesian wells in glacial drift and bedrock.

38. The Illinois glacial lobe, by Frank Leverett. 1899. 817 pp., 24 pls. $1.60.

Includes a chapter (pp. 550-788) on "Wells of Illinois," which contains a general discussion of artesian and other wells, a table of municipal water supplies derived from underground sources, and a detailed description of wells and ground-water conditions in practically every county in the State. The monograph includes maps showing the geology, the distribution of wells, the intake areas of "Potsdam" and St. Peter sandstones, and the relation of glacial drift to ground-water supplies.

PROFESSIONAL PAPERS.

Professional papers are distributed free by the Geological Survey as long as its stock lasts. An asterisk (*) indicates that this stock has been exhausted. Many of the papers marked with an asterisk may, however, be purchased from the SUPERINTENDENT OF DOCUMENTS, WASHINGTON, D. C. Professional papers are of quarto size.

*32. Preliminary report on the geology and underground-water resources of the central Great Plains, by N. H. Darton. 1905. 433 pp., 72 pls. $1.80.

Covers South Dakota, Nebraska, central and western Kansas, eastern Colorado, and eastern Wyoming. Describes the geography, geology, and water horizons; gives deep-well data and well prospects by counties; also describes other mineral resources. Includes maps showing the geology, location of deep wells, structure of the Dakota sandstone, depths to this sandstone head of artesian water, and areas of artesian flow.

BULLETINS.

An asterisk (*) indicates that the Geological Survey's stock of the paper is exhausted. Many of the papers so marked may be purchased from the SUPERINTENDENT OF DOCUMENTS, WASHINGTON, D. C.

*264. Record of deep-well drilling for 1904, by M. L. Fuller, E. F. Lines, and A. C. Veatch. 1905. 106 pp. 10c.

Discusses the importance of accurate well records to the driller, to owners of oil, gas, and water wells, and to the geologist; describes the general methods of work; gives tabulated records of wells in Illinois and Iowa, and detailed records of wells in Boone, Dupage, Henry, and La Salle counties, Ill., and Des Moines and Scott counties, Iowa. These wells were selected because they give definite stratigraphic information.

*298. Record of deep-well drilling for 1905, by M. L. Fuller and Samuel Sanford. 1906. 299 pp. 25c.

Gives an account of progress in the collection of well records and samples; contains tabulated records of wells in Illinois, Indiana, Iowa, Minnesota, Missouri, North Dakota, South Dakota, and Wisconsin; and detailed records of wells in Brown, Hancock, La Salle, Pike, and Schuyler counties, Ill.; Blackhawk, Floyd, Louisa, Mahaska, Scott, and Wapello counties, Iowa; and Hennepin, Ottertail, and Pine counties, Minn. The wells of which detailed sections are given were selected because they afford valuable stratigraphic information.

GEOLOGIC FOLIOS.

Under the plan adopted for the preparation of a geologic map of the United States the entire area is divided into small quadrangles bounded by certain meridians and parallels, and these quadrangles, which number several thousand, are separately surveyed and mapped.[1] The unit of survey is also the unit of publication, and the maps and description of each quadrangle are issued in the form of a folio. When all the folios are completed they will constitute the Geologic Atlas of the United States.

A folio is designated by the name of the principal town or of a prominent natural feature within the quadrangle. Each folio includes maps showing the topography, geology, underground structure, and mineral deposits of the area mapped and several pages of descriptive text. The text explains the maps and describes the topographic and geologic features of the country and its mineral products. The topographic map shows roads, railroads, waterways, and, by contour lines, the shapes of hills and valleys and the height above sea level of all points in the qaudrangle. The areal-geology map shows the distribution of the various rocks at the surface. The structural-geology map shows relations of the rocks to one another underground. The economic-geology map indicates the location of mineral deposits that are commercially valuable. The artesian water map shows the depth to underground-water horizons. Economic-geology and artesian-water maps are included in folios if the conditions in the areas mapped warrant their publication. The folios are of special interest to students of geography and geology and are valuable as guides in the development and utilization of mineral resources.

The folios numbered from 1 to 163, inclusive, are published in only one form (18 by 22 inches), called the library edition. Some of the folios that bear numbers higher than 163 are published also in an octavo edition (6 by 9 inches). Owing to a fire in the Geological Survey building May 18, 1913, the stock of geologic folios was more or less damages by fire and water, but 80 or 90 per cent of the folios are usable. They will be sold at the uniform price of 5 cents each, with no reduction for wholesale orders. This rate applies to folios in stock from 1 to 184, inclusive (except reprints), also to the library edition of folio 186. The library edition of folios 185, 187, and higher numbers sells for 25 cents a copy, except that some folios which contain an unusually large amount of matter sell at higher prices. The octavo edition of folio

[1] Index maps showing areas in the Hudson Bay and upper Mississippi River basins covered by topographic maps and by geologic folios will be mailed on receipt of request addressed to the Director, U. S. Geological Survey, Washington, D. C.

185 and higher numbers sells for 50 cents a copy. A discount of 40 per cent is allowed on an order for folios or for folios together with topographic maps amounting to $5 at the retail rate.

All the folios contain descriptions of the drainage of the quadrangles. The folios in the following list contain also a brief discussion of the underground waters in connection with the economic resources of the areas and more or less information concerning the utilization of the water resources.

An asterisk (*) indicates that the stock of the folio is exhausted.

117. Casselton-Fargo, North Dakota-Minnesota. 5c.

Gives a somewhat detailed account of the water supply, including descriptions and logs of principal wells and tabulated well records, contains artesian-water maps showing areas which will probably yield flowing wells.

*145. Lancaster-Mineral Point, Wisconsin-Iowa-Illinois.

Discusses the springs, shallow and deep wells, streams and water power; gives analyses of artesian water from well at Dubuque, Iowa.

168. Jamestown-Tower (Jamestown, Eckelson, and Tower quadrangles), North Dakota.[1] 5c.

Discusses shallow, deep, and artesian wells; head, pressure, power, volume, and character of the water, and gives a tabulated list of representative wells; contains an artesian-water map showing areas in which flowing wells may probably be obtained.

185. Murphysboro-Herrin, Illinois.[1] Library edition, 25c., octavo edition, 50c.

188. Tallula-Springfield, Illinois.[1] Library edition, 25c., octavo edition, 50c.

Discusses wells and the wholesomeness of the water; gives analyses of water from wells in the city of Springfield.

195. Belleville-Breese, Illinois. 25c.

Discusses wells and gives analyses of water from springs and wells.

200. Galena-Elizabeth, Illinois-Iowa. 25c.

201. Minneapolis-St. Paul, Minnesota.[1] Library edition, 25c., octavo edition, 50c.

MISCELLANEOUS REPORTS.

Other Federal bureaus and the State and other organizations have from time to time published reports relating to the water resources of the various sections of the country. Notable among those pertaining to the Hudson Bay and upper Mississippi River basins are the reports of the State surveys of Illinois and North Dakota, the Wisconsin Geological and Natural History Survey and the Railroad Commission of Wisconsin, the Illinois Water-Supply Commission, and the Rivers and Lakes Commission of Illinois, and the water-power report of the Tenth Census (vol. 17). The following reports deserve special mention:

Contributions to the physical geography of the United States, Part I. On the physical geography of the Mississippi Valley, with suggestions for the improvement of navigation of the Ohio and other rivers, by Charles Ellet, jr.: Smithsonian Pub. 13, Washington, 1850.

The Mississippi and Ohio rivers, by Charles H. Ellet. 1853.

Report upon the physics and hydraulics of the Mississippi River, by A. A. Humphreys and H. L. Abbott.

[1] Issued in two editions; specify which edition is wanted.

The mineral content of Illinois waters, by Edward Barstow, J. A. Udden, S. W. Parr, and George T. Palmer: Illinois State Geol. Survey Bull. 10, 1909.

Water resources of the East St. Louis district, by Isaiah Bowman: Illinois State Geol. Survey Bull. 5, 1907.

Chemical and biological survey of waters of Illinois, by Edward Bartow: Univ. Illinois Pub. 3, 6, 7, 1906–1909.

Chemical survey of the waters of Illinois, report for the years 1897–1902, by A. W. Palmer, with report on geology of Illinois as related to its water supply, by Charles W. Rolfe: Univ. Illinois Pub.

Report and plans for the reclamation of lands subject to overflow in the Kaskaskia River Valley, Illinois; begun under the direction of the Internal Improvement Commission; completed and published under the direction of the Rivers and Lakes Commission of Illinois, by Jacob A. Harman. 1912.

Diversion of the waters of the Great Lakes by way of the sanitary and ship canal of Chicago: A brief of the facts and issues, by Lyman E. Cooley, Chicago. 1913.

The State of Missouri *vs.* the State of Illinois and the Sanitary district of Chicago, before Frank S. Bright, Commissioner of the Supreme Court of the United States. 1904.

The mineral waters of Indiana, their location, origin, and character, by W. S. Blatchley: Indiana Dept. Geology and Nat. Res. Twenty-sixth Ann. Rept., 1901.

Report of the water-resources investigation of Minnesota by the State drainage commission, 1910.

Report of the commission on conservation [Montana] on bills relating to the public lands, water rights, and the protection and preservation of the forests, 1911.

Governor's message relating to conservation [in Montana] on bills relating to public lands, water rights, and the protection and preservation of the forests.

Water resources of the Devils Lake region, North Dakota, by E. J. Babcock: North Dakota Geol. Survey, Second Bienn. Rept., 1903.

The water powers of Wisconsin, by Leonard S. Smith: Wisconsin Geol. and Nat. Hist. Survey Bull. 20. Madison, Wis., 1908.

Report of the Railroad Commission of Wisconsin to the legislature on water powers. Madison, Wis., 1915.

Many of these reports can be obtained by applying to the several organizations, and most of them can be consulted in the public libraries of the larger cities.

GEOLOGICAL SURVEY HYDROLOGIC REPORTS OF GENERAL INTEREST.

The following list comprises reports not readily classifiable by drainage basins and covering a wide range of hydrologic investigations:

WATER-SUPPLY PAPERS.

*1. Pumping water for irrigation, by H. M. Wilson. 1896. 57 pp., 9 pls.

Describes pumps and motive powers, windmills, water wheels, and various kinds of engines; also storage reservoirs to retain pumped water until needed for irrigation.

*3. Sewage irrigation, by G. W. Rafter. 1897. 100 pp., 4 pls. (See Water-Supply Paper 22.) 10c.

Discusses methods of sewage disposal by intermittent filtration and by irrigation; describes utilization of sewage in Germany, England, and France, and sewage purification in the United States.

*8. Windmills for irrigation, by E. C. Murphy. 1897. 49 pp., 8 pls. 10c.

Gives results of experimental tests of windmills during the summer of 1896 in the vicinity of Garden, Kansas; describes instruments and methods and draws conclusions.

*14. New tests of certain pumps and water lifts used in irrigation, by O. P. Hood. 1898. 91 pp., 1 pl.

Discusses efficiency of pumps and water lifts of various types.

*20. Experiments with windmills, by T. O. Perry. 1899. 97 pp., 12 pls. 15c.

Includes tables and descriptions of wind wheels, compares wheels of several types, and discusses results.

*22. Sewage irrigation, Part II, by G. W. Rafter. 1899. 100 pp., 7 pls. 15c.

Gives résumé of Water-Supply Paper 3; discusses pollution of certain streams, experiments on purification of factory wastes in Massachusetts, value of commercial fertilizers, and describes American sewage-disposal plants by States; contains bibliography of publications relating to sewage utilization and disposal.

*41. The windmill; its efficiency and economic use, Part I, by E. C. Murphy. 1901. 72 pp., 14 pls. 5c.

*42. The windmill; its efficiency and economic use, Part II, by E. C. Murphy. 1901. 75 pp. (73–147), 2 pls. (15–16). 10c.

Nos. 41 and 42 give details of results of experimental tests with windmills of various types.

*43. Conveyance of water in irrigation canals, flumes, and pipes, by Samuel Fortier. 1901. 86 pp., 15 pls. 15c.

*56. Methods of stream measurement. 1901 51 pp., 12 pls. 15c.

Describes the methods used by the Survey in 1901-2. (See also Nos. 64, 94, and 95.)

*64. Accuracy of stream measurements, by E. C. Murphy. 1902. 99 pp. 4. pls. (See No. 95.) 10c.

Describes methods of measuring velocity of water and of measuring and computing stream flow, and compares results obtained with the different instruments and methods; describes also experiments and results at the Cornell University hydraulic laboratory. A second, enlarged, edition published as Water-Supply Paper 95.

*67. The motions of underground waters, by C. S. Slichter. 1902. 106 pp., 8 pls. 15c.

Discusses origin, depth, and amount of ground waters; permeability of rocks and porosity of soils; causes, rates, and laws of motions of ground waters; surface and deep zones of flow, and recovery of waters by open wells and artesian and deep wells; treats of the shape and position of the water table; gives simple methods of measuring yields of flowing wells; describes artesian wells at Savannah, Ga.

72. Sewage pollution in the metropolitan area near New York City and its effect on inland water resources, by M. O. Leighton. 1902. 75 pp., 8 pls. 10c.

Defines "normal" and "polluted" waters and discusses the damage resulting from pollution.

*80. The relation of rainfall to run-off, by G. W. Rafter. 1903. 104 pp. 10c.

Treats of measurements of rainfall and laws and measurements of streams flow: gives formulas for rainfall, run-off, and evaporation; discusses effects of forests on rainfall and run-off.

87. Irrigation in India (second edition), by H. M. Wilson. 1903. 238 pp., pls. 25c.

First edition was published in Part II of the Twelfth Annual Report.

93. Proceeding of first conference of engineers of the Reclamation Service, with accompanying papers, compiled by F. H. Newell, Chief Engineer. 1904. 361 pp. 25c. [Requests for this report should be addressed to the U. S. Reclamation Service.]

Contains the following papers of more or less general interest:
Limits of an irrigation project, by D. W. Ross.
Relation of Federal and State laws to irrigation, by Morris Bien.
Electrical transmission of power for pumping, by H. A. Storrs.
Correct design and stability of high masonry dams, by Geo. Y. Wisner.
Irrigation surveys and use of the plane table, by J. V. Lippincott.
The use of alkaline waters for irrigation, by Thomas H. Means.

*94. Hydrographic manual of the United States Geological Survey, prepared by E. C. Murphy, J. C. Hoyt, and G. B. Hollister. 1904. 76 pp., 3 pls. 10c.

Gives instruction for field and office work relating to measurements of stream flow by current meters. (See also No. 95.)

*95. Accuracy of stream measurements (second, enlarged edition), by E. C. Murphy 1904. 169 pp., 6 pls.

Describes methods of measuring and computing stream flow and compares results derived from different instruments and methods. (See also No. 94.)

*103. A review of the laws forbidding pollution of inland water in the United States, by E. B. Goodell. 1904. 120 pp. (See No. 152.)

Explains the legal principles under which antipollution statues become operative, quotes court decisions to show authority for various deductions, and classifies according to scope the statutes enacted in the different States.

110. Contributions to the hydrology of Eastern United States; 1904, M. L. Fuller, geolgist in charge. 1905. 211 pp., 5 pls. 10c.

Contains the following reports of general interest. The scope of each paper is indicated by its title.
Description of under flow meter used in measuring the velocity and direction of underground water, by Charles S. Slichter.
The California or "stovepipe" method of well construction, by Charles S. Slichter.
Approximate methods of measuring the yield of flowing wells, by Charles S. Slichter.
Corrections necessary in accurate determinations of flow from verticals well casings, from notes furnished by A. N. Talbot.

113. The disposal of strawboard and oil-well wastes, by R. L. Sackett and Isaiah Bowman. 1905. 52 pp., 4 pls. 5c.

The first paper discusses the pollution of stream by sewage and by trade wastes, describes the manufacture of strawboard, and gives results of various experiments in disposing of the waste. The second paper describes briefly the topography, drainage, and geology of the region about Marion, Ind., and the contamination of rock wells and of streams by waste oil and brine.

*114. Underground waters of eastern United States; M. L. Fuller, geologist in charge. 1905. 285 pp., 18 pls. 25c.

Contains reports on "Occurrence of underground waters," by M. L. Fuller, discussing sources, amount, and temperature of waters, permeability and storage capacity of rocks, water-bearing formations, recovery of water by springs, wells, and pumps, essential conditions of artesian flows, and general conditions affecting ground waters in eastern United States.

119. Index to the hydrographic progress reports of the United States Geological Survey, 1888 to 1903, by J. C. Hoyt and B. D. Wood. 1905. 253 pp. 15c.

120. Bibliographic review and index of papers relating to underground waters published by the United States Geological Survey, 1879–1904, by M. L. Fuller 1905. 128 pp. 10c.

*122. Relation of the law to underground waters, by D. W. Johnson. 1905. 55 pp. 5c.

Defines and classifies underground waters, gives common-law rules relating to their use and cities State legislative acts affecting them.

140. Field measurements of the rate of movement of underground waters, by C. S. Slitcher. 1905. 122 pp., 15 pls. 15c.

Discusses the capacity of sand to transmit water, describes measurements of underflow in Rio Hondo, San Gabriel, and Mohave River valleys, Cal., and on Long Island, N. Y., gives results of tests of wells and pumping plants, and describes stovepipe method of well construction.

143. Experiments on steel-concrete pipes on a working scale, by J. H. Quinton. 1905. 61 pp., 4 pls. 5c.

Scope indicated by title.

145. Contributions to the hydrology of eastern United States, 1905; M. L. Fuller, geologist in charge. 1905. 220 pp., 6 pls. 10c.

Contains brief reports of general interest as follows:

Drainage of ponds into drilled wells, by Robert E. Horton. Disscuses efficiency, cost, and capacity of drainage wells, and gives statistics of such well in Southern Michigan.

Construction of so-called fountain and geyser springs, by Myron L. Fuller.

A convenient gage for determining low artesian heads, by Myron L. Fuller.

146. Proceedings of second conference of engineers of the Reclamation Service, with accompanying papers, compiled by F. H. Newell, Chief Engineer. 1905. 267 pp. 15c. [Inquiries concerning this report should be addressed to the Reclamation Service.]

Contains brief account of the organization of the hydrographic [water-resources] branch and the Reclamation Service, reports of conferences and committees, circulars of instruction, and many brief reports on subjects closely related to reclamation, and a bibiliography of technical papers by members of the service. Of the papers read at the conference those listed below (scope indicated by title) are of more or less general interest.

Proposed State code of water laws, by Morris Bien.
Power engineering applied to irrigation problems, by O. H. Ensign.
Estimates on tunneling in irrigation projects, by A. L. Fellows
Collection of steam-gaging data, by N. C. Grover.
Diamond-drill methods, G. A. Hammond.
Mean-velocity and area curves, by F. W. Hanna.
Importance of general hydrographic data concerning basins of streams gaged, by R. E. Horton.
Effect of aquatic vegetation on stream flow, by R. E. Horton.
Sanitary regulations governing construction camps, by M. O. Leighton.
Necessity of draining irrigated land, by Thos. H. Means.
Alkali soils, by Thos. H. Means.
Cost of stream gaging work, by E. C. Murphy.
Equipment of a cable gaging station, by E. C. Murphy.
Silting of reservoirs, by W. M. Reed.
Farm-unit classification, by D. W. Ross.
Cost of power for pumping irrigated water, by H. A. Storrs.
Records of flow at current-meter gaging stations during the frozen season, by F. H. Tillinghast.

147. Destructive floods in United States in 1904, by E. C. Murphy and others. 1905. 206 pp., 18 pls. 15c.

Contains a brief account of "A method of computing cross-section area of waterways," including formulas for maximum discharge and areas of cross section.

*150. Weir experiments, coefficients, and formulas, by R. E. Horton. 1906. 189 pp., 38 pls. (See Water-Supply Paper 200.) 15c.

Scope indicated by title.

151. Field assay of water, by M. O. Leighton. 1905. 77 pp., 4 pls.

Discusses methods, instruments, and reagents used in determining turbidity, color, iron, chlorides, and hardness in connection with the studies of the quality of water in various parts of the United States.

*152. A review of the laws forbidding pollution of inland waters in the United States, second edition, by E. B. Goodell. 1905. 149 pp.

Scope indicated by title.

*155. Fluctuations of the water level in wells, with special reference to Long Island. N. Y., A. C. Veatch. 1906. 83 pp., 9 pls. 25c.

Includes general discussion of fluctuations due to rainfall and evaporation, barometric changes, temperature changes, changes in rivers, changes in lake level, tidal changes, effects of settlement, irrigation, dams, underground-water developments, and to indeterminate causes.

*160. Underground water papers. 1906; M. L. Fuller, geologist in charge. 1906. 104 pp., 1 pl.

Gives account of work in 1905; lists publications relating to underground waters, and contains the following brief reports of general interest:

Significance of the term "artesian," by Myron L. Fuller.
Representation of wells and springs on maps, by Myron L. Fuller.
Total amount of free water in the earth's crust, by Myron L. Fuller.
Use of fluorescein in the study of underground waters, by R. B. Dole.
Problems of water contamination, by Isaiah Bowman.
Instances of improvement of water in wells, by Myron L. Fuller.

*162. Destructive floods in the United States in 1905, with a discussion of flood discharge and frequency and an index to flood literature, by E. C. Murphy and others. 1906. 105 pp., 4 pls. 15c.

*163. Bibligoraphic review and index of underground-water literature published in the United States in 1905, by M. L. Fuller, F. G. Clapp, and B. L. Johnson. 1906. 130 pp. 15c.

Scope indicated by title.

*179. Prevention of stream pollution by distillery refuse, based on investigations at Lynchburg, Ohio, by Herman Stabler. 1906. 34 pp., 1 pl. 10c.

Describes grain distillation, treatment of slop, sources, character, and effects of effluents on streams; discusses filtration, precipitation, fermentation, and evaporation methods of disposal of wastes without pollution.

*180. Turbine water-wheel tests and power tables, by R. E. Horton. 1906. 134 pp., 2 pls. 20c.

Scope indicated by title.

*185. Investigations on the purification of Boston sewage, * * * with a history of the sewage-disposal problem, by C.-E. A. Winslow and E. B. Phelps. 1906. 163 pp. 25c.

Discusses composition, disposal, purification, and treatment of sewages and tendencies in sewage-disposal practice in England, Germany, and the United States; describes character of crude sewage at Boston, removal of suspended matter, treatment in septic tanks, and purification by intermittent sand filtration and in beds of course material; gives bibliography.

*186. Stream pollution by acid-iron wastes, a report based on investigations made at Shelby, Ohio, by Herman Stabler. 1906. 36 pp., 1 pl.

Gives history of pollution by acid-iron wastes at Shelby, Ohio, and of resulting litigation; discusses effect of acid-iron liquors of sewage-purification processes, recovery of copperas from acid-iron wastes, and other processes for removal of pickling liquor.

*187. Determination of stream flow during the frozen season, by H. K. Barrows and R. E. Horton. 1907. 93 pp., 1 pl. 15c.

Scope indicated by title.

*189. The prevention of stream pollution by strawboard waste, by E. B. Phelps. 1906. 29 pp., 2 pls.

Describes manufacture of strawboard, present and proposed methods of disposal of waste liquors, laboratory investigations of precipitation and sedimentation, and field studies of amounts and character of water used, raw material and finished product, and mechanical filtration.

*194. Pollution of Illinois and Mississippi rivers by Chicago sewage (a digest of the testimony taken in the case of the State of Missouri v. The State of Illinois and the Sanitary District of Chicago), by M. O. Leighton. 1907. 369 pp., 2 pls.

Scope indicated by amplification of title.

*200. Weir experiments, coefficients, and formulas (revision of paper No. 150), by R. E. Horton. 1907. 195 pp., 1 pl. 35c.

Scope indicated by title.

*226. The pollution of streams by sulphite-pulp waste, a study of possible remedies by E. B. Phelps. 1909. 37 pp., 1 pl. 10c.

Describes manufacture of sulphite pulp, the waste liquors, and the experimental work leading to suggestions as to methods of preventing stream pollution.

*229. The disinfection of sewage and sewage filter effluents, with a chapter on the putrescibility and stability of sewage effluents, by E. B. Phelps. 1909. 91 pp., 1 pl. 15c.

Scope indicated by title.

*234. Papers on the conversion of water resources. 1909. 96 pp., 2 pls. 15c.

Contains the following papers, whose scope is indicated by their titles: Distribution of fall, by Henry Gannett; Floods, by M. O. Leighton; Developed water powers, compiled under the direction of W. M. Steuart, with discussion by M. O. Leighton; Undeveloped water powers, by M. O. Leighton; Irrigation, by F. H. Newell; Underground waters, by W. C. Mendenhall; Denudation, by R. B. Dole and Herman Stabler; Control of catchment areas, by H. N. Parker.

*235. The purification of some textile and other factory wastes, by Herman Stabler. and G. H. Pratt. 1909. 76 pp. 10c.

Discusses waste waters from wool-scouring, bleaching, and dyeing cotton yarn, bleaching cotton piece goods, and manufacture of oleomargarine, fertilizer, and glue.

236. The quality of surface waters in the United States: Part I, Analyses of waters east of the one hundredth meridian, by R. B. Dole. 1909. 123 pp. 10c.

Describes collection of samples, methods of examination, preparation of solutions, accuracy of estimates, and expression of analytical results.

238. The public utility of water powers and their governmental regulation, by René Tavernier and M. O. Leighton. 1910. 161 pp. 15c.

Discusses hydraulic power and irrigation, French, Italian, and Swiss legislation relative to the development of water powers, and laws proposed in the French Parliament; reviews work of bureau of hydraulics and agricultural improvement of the French department of agriculture and gives résumé of Federal and State water-power legislation in the United States.

*255. Underground waters for farm use, by M. L. Fuller. 1910. 58 pp., 17 pls. 15c.

Discusses rocks as sources of water supply and the relative saftey of supplies from different materials; springs, and their protection; open or dug and deep wells, their location, yields, relative cost, protection, and safety; advantages and disadvantages of cisterns and combination wells and cisterns.

*257. Well-drilling methods, by Isaiah Bowman. 1911. 139 pp., 4 pls. 15c.

Discusses amount, distribution, and disposal of rainfall, water-bearing rocks, amount of ground water, artesian conditions, and oil and gas bearing formations; gives history of well drilling in Asia, Europe, and the United States; describes in detail the various methods and the machinery used; discusses loss of tools and geologic difficulties; contamination of well waters and methods of prevention; tests of capacity and measurement of depth; and costs of sinking wells.

*258. Underground water papers, 1910, by M. L. Fuller, F. G. Clapp, G. C. Matson, Samuel Sanford, and H. C. Wolff. 1911. 123 pp., 2 pls. 15c.

Contains the following papers (scope indicated by titles) of general interest:
Drainage by wells, by M. L. Fuller.
Freezing of wells and related phenomena, by M. L. Fuller.
Pollution of underground waters in limestone, by G. C. Matson.
Protection of shallow wells in sandy deposits, by M. L. Fuller.
Magnetic wells, by M. L. Fuller.

274. Some stream waters of the western United States, with chapters on sediment carried by the Rio Grande and the industrial application of water analyses, by Herman Stabler. 1911. 188 pp. 15c.

Describes collection of samples, plan of analytical work, and methods of analyses; discusses soap-consuming power of waters, water softening, boiler waters, and water for irrigation.

*315. The purification of public water supplies, by G. A. Johnson. 1913. 84 pp., 8 pls. 10c.

Discusses ground, lake, and river waters as public supplies, development of waterworks systems in the United States, water consumption, and typhoid fever; describes methods of filtration and sterlization of water, and municipal water softening.

334. The Ohio Valley flood of March–April, 1913 (including comparisons with some earlier floods), by A. H. Horton and H. J. Jackson. 1913. 96 pp., 22, pls. 20c.

Although relating specifically to floods in the Ohio Valley, this report discusses also the causes of floods and the prevention of damage by floods.

337. The effects of ice on stream flow, by William Glenn Hoyt. 1913. 77 pp., 7 pls. 15c.

Discusses methods of measuring the winter flow of streams.

*345. Contributions to the hydrology of the United States, 1914; N. C. Grover, chief hydraulic engineer. 1915. 225 pp., 17 pls. 30c. Contains:

(e) A method of determining the daily discharge of rivers of variable slope, by M. R. Hall, W. E. Hall, and C. H. Pierce, pp. 53–65.

364. Water analyses from the laboratory of the United States Geological Survey, tabulated by F. W. Clarke, chief chemist. 1914; 40 pp 5c.

Contains analyses of waters from rivers, lakes, wells, and springs in various parts of the United States, including analyses of the geyser water of Yellowstone National Park, hot springs in Montana, brines from Death Valley, water from the Gulf of Mexico, and mine waters from Tennessee, Michigan, Missouri and Oklahoma, Montana, Colorado, and Utah, Nevada and Arizona, and California.

371. Equipment for current-meter gaging stations, by G. J. Lyon. 1915. 64 pp., 37 pls. 20c.

Describes methods of installing automatic and other gages and of constructing gage wells, shelters, and structures for making discharge measurements and artificial controls.

*375. Contributions to the hydrology of the United States, 1915; N. C. Grover, chief hydraulic engineer. 1916. 181 pp., 9 pls. 15c.

Contains three papers presented at the conference of engineers of the water-resources branch in December, 1914.

* (c) The relation of steam gaging to the science of hydraulics, by C. H. Pierce and R. W. Davenport, pp. 77–84.

(e) A method for correcting river discharge for changing stage, by B. E. Jones, pp. 117–130.

(f) Conditions requiring the use of automatic gages in obtaining records of steam flow, by C. H. Pierce, pp. 131–139.

*400. Contributions to the hydrology of the United States, 1916; N. C. Grover, chief hydraulic engineer. 1917. 108 pp., 7 pls. Contains:

(a) The people's interest in water-power resources, by G. O. Smith, pp. 1-8.
* (c) The measurement of silt-laden streams, by R. C. Pierce, pp. 39-51.
(d) Accuracy of stream-flow data, by N. C. Grover and J. C. Hoty, pp. 53-59.

416. The divining rod, a history of water witching, with a bibliography, by Arthur J. Ellis. 1917. 59 pp. 10c.

A brief paper published "merely to furnish a reply to the numerous inquiries that are continually being received from all parts of the country" as to the efficacy of the divining rod for locating underground water.

425. Contributions to the hydrology of the United States, 1917; N. C. Grover, chief hydraulic engineer. 1918. Contains:

(c) Hydraulic conversion tables and convenient equivalents, pp. 71-94. 1917.

427. Bibliography and index of the publications of the United States Geological Survey relating to ground water, by O. E. Meinzer. 1918. 169 pp., 1 pl.

Includes publications prepared, in whole or part, by the Geological Survey that treat any phase of the subject of ground water or any subject directly applicable to ground water. Illustrated by map showing reports that cover specific areas more or less thoroughly.

ANNUAL REPORTS.

*Fifth Annual Report of the United States Geological Survey, 1883-84, J. W. Powell, Director. 1885. xxxvi, 469 pp., 58 pls. $2.25. Contains:

* The requisite and qualifying conditions of artesian wells, by T. C. Chamberlin, pp. 125-173, pl. 21. Scope indicated by title.

Twelfth Annual Report of the United States Geological Survey, 1890-91, J. W. Powell, Director. 1891. 2 parts. *Pt. II, Irrigation, xviii, 576 pp., 93 pls. $2. Contains:

* Irrigation in India, by H. M. Wilson, pp. 368-561, pls. 107 to 146. See Water-Supply Paper 87.

Thirteenth Annual Report of the United States Geological Survey, 1891-92, J. W. Powell, Director. 1892. (Pts. II and III, 1893.) 3 parts. *Pt. III, Irrigation, xi, 486 pp., 77 pls. $1.85. Contains:

* American irrigation engineering, by H. M. Wilson, pp. 101-349, pls. 111 to 145. Discusses the economic aspects of irrigation, alkaline drainage, silt and sedimentation; gives brief history of legislation; describes perennial canals in Idaho, California, Wyoming, and Arizona; discusses water storage at reservoirs of the California and other projects, subsurface sources of supply, pumping, and subirrigation.

Fourteenth Annual Report of the United States Geological Survey, 1892-93, J. W., Powell, Director. 1893. (Pt. II, 1894.) 2 parts. *Pt. II, Accompanying papers, xx, 597 pp., 73 pls. $2.10. Contains:

* Potable waters of the eastern United States, by W J McGee, pp. 1 to 47. Discusses cistern water, stream waters, and ground waters, including mineral springs and artesian wells.

* Natural mineral waters of the United States, by A. C. Peale, pp. 49-88, pls. 3 and 4. Discusses the origin and flow of mineral springs, the source of mineralization, thermal springs, the chemical composition and analysis of spring waters, geographic distribution, and the utilization of mineral waters; gives a list of American mineral spring resorts; contains also some analyses.

Nineteenth Annual Report of the United States Geological Survey, 1897-98, Charles D. Walcott, Director. 1898. (Parts II, III, and V, 1899.) 6 parts in 7 vols. and separate case for maps with Pt. V. *Pt. II.—Papers chiefly of a theoretic nature, v, 958 pp., 172 pls. $2.65. Contains:

* Principles and conditions of the movements of ground water, by F. H. King, pp. 59-294, pls. 6 to 16. Discusses the amount of water stored in sandstone, in soil, and in other rocks, the depth to which ground water penetrates; gravitational, thermal, and capillary movements of ground waters, and the configuration of the ground-water surface; gives the results of experimental investigations on the flow of air and water through a rigid, porous medium and through

sands, sandstones, and silts; discusses results obtained by other investigators, and summarizes results of observations; discusses also rate of flow of water through sand and rock, the growth of rivers, rate of filtration through soil, interference of wells, etc.

* Theoretical investigation of the motion of ground waters, by C. S. Slichter, pp. 295–384, pl. 17. Scope indicated by title.

PROFESSIONAL PAPERS.

*72. Denudation and erosion in the southern Appalachian region and the Monongahela basin, by L. C. Glenn. 1911. 137 pp., 21 pls. 35c.

Describes the topography, geology, drainage, forests, climate and population, and transportation facilities of the region, the relation of agricultural lumbering, mining, and power development to erosion and denudation, and the nature, effects, and remedies of erosion; gives details of conditions in Holston, Nolichucky, French Broad, Little Tennessee, and Hiwassee river basins, along Tennessee River proper, and in the basins of the Coosa-Alabama system, Chattahoochee, Savannah, Saluda, Broad, Catawba, Yadkin, New, and Monongahela rivers.

86. The transportation of débris by running water, by G. K. Gilbert, based on experiments made with the assistance of E. C. Murphy. 1914. 263 pp., 3 pls. 70c.

The results of an investigation which was carried on in a specially equipped laboratory at Berkeley, Cal., and was undertaken for the purpose of learning "the laws which control the movement of bed load and especially to determine how the quantity of load is related to the stream slope and discharge and to the degree of comminution of the débris."

105. Hydraulic-mining débris in the Sierre Nevada, by G. K. Gilbert. 154 pp., 34 pls. 1917. 50c.

Presents the results of an investigation undertaken by the United States Geological Survey in response to a memorial from the California Miners' Association asking that a particular study be made of portions of the Sacramento and San Joaquin valleys affected by detritus from torrential streams. The report deals largely with geologic and physiographic aspects of the subject, traces the physical effects, past and future, of the hydraulic mining of earlier decades, the similar effects which certain other industries induce through stimulation of the erosion of the soil, and the influence of the restriction of the area of inundation by the construction of levees. Suggests cooperation by several interests for the control of the streams now carrying heavy loads of débris.

BULLETINS.

*32. Lists and analyses of the mineral springs of the United States (a preliminary study), by A. C. Peale. 1886. 235 pp.

Defines mineral waters, lists the springs by State, and gives table of analyses.

*319. Summary of the controlling factors of artesian flows, by Myron L. Fuller. 1908. 44 pp. 7 pls. 10c.

Describes underground reservoirs, the source of ground waters, the confining agents, the primary and modifying factors of artesian circulation, the essential and modifying factors of artesian flow, and typical artesian systems.

*479. The geochemical interpretation of water analyses, by Chase Palmer. 1911. 31 pp. 5c.

Discusses the expression of chemical analyses, the chemical character of water and the properties of natural waters; gives a classification of waters based on property values and reacting values, and discusses the character of the waters of certain rivers as interpreted directly from the results of analyses; discusses also the relation of water properties to geological formations, silica in river water, and the character of the water of the Mississippi and the Great Lakes and St. Lawrence River as indicated by chemical analyses.

616. The data of geochemistry (third edition), by F. W. Clarke. 1916. 821 pp. 45c.

Earlier editions were published as Bulletins 330 and 491. Contains a discussion of the statement and interpretation of water analyses and a chapter on "Mineral wells and springs" (pp. 179-216). Discusses the definition and classification of mineral waters, changes in composition of water, deposits of calcareous, ocherous, and siliceous materials made by water, vadose and juvenile waters, and thermal springs in relation to volcanism. Describes the different kinds of ground water and gives typical analyses. Includes a brief bibliography of papers containing water analyses.

INDEX BY AREAS AND SUBJECTS.

[A=Annual Reports; M=Monograph; B=Bulletin; P=Professional Paper; W=Water-Supply Paper, G F=Geologic folio.]

[1] Many of the reports contain brief subject bibliographies See abstracts.

[2] Many analyses of river, spring, and well waters are scattered through publications, as noted in abstracts.

SURFACE WATER SUPPLY OF MISSOURI RIVER BASIN, 1917.

AUTHORIZATION AND SCOPE OF WORK.

This volume is one of a series of 14 reports presenting results of measurement of flow made on streams in the United States during the year ending September 30, 1917.

The data presented in these reports were collected by the United States Geological Survey under the following authority contained in the organic law (20 Stat. L., p. 394):

Provided, That this officer [the Director] shall have the direction of the Geological Survey and the classification of public lands and examination of the geological structure, mineral resources, and products of the national domain.

The work was begun in 1888 in connection with special studies relating to irrigation in the arid West. Since the fiscal year ending June 30, 1895, successive sundry bills passed by Congress have carried the following item and appropriations:

For gaging the streams and determining the water supply of the United States, and for the investigation of underground currents and artesian wells, and for the preparation of reports upon the best methods of utilizing the water resources.

Annual appropriation for the fiscal years ending June 30, 1895–1918.

1895	$12,500
1896	20,000
1897 to 1900, inclusive	50,000
1901 to 1902, inclusive	100,000
1903 to 1906, inclusive	200,000
1907	150,000
1908 to 1910, inclusive	100,000
1911 to 1917, inclusive	150,000
1918	175,000

In the execution of the work many private and State organizations have cooperated either by furnishing data or by assisting in collecting data. Acknowledgments for cooperation of the first kind are made in connection with the description of each station affected; cooperation of the second kind is acknowledged on page 11.

Measurements of stream flow have been made at about 4,240 points in the United States and also at many points in Alaska and the Hawaiian Islands. In July, 1917, 1,180 gaging stations were being maintained by the Survey and the cooperating organizations. Many miscellaneous discharge measurements are made at other points. In connection with this work data were also collected in regard to precipitation, evaporation, storage reservoirs, river profiles, and water power in many sections of the country and will be made available in water-supply papers from time to time. Information in regard to publications relating to water resources is presented in the appendix to this report.

DEFINITION OF TERMS.

The volume of water flowing in a stream—the "run-off" or "discharge"—is expressed in various terms, each of which has become associated with a certain class of work. These terms may be divided into two groups—(1) those that represent a rate of flow, as second-feet, gallons per minute, miner's inches, and discharge in second-feet per square mile, and (2) those that represent the actual quantity of water, as run-off in depth in inches, acre-feet, and millions of cubic feet. The principal terms used in this series of reports are second-feet, second-feet per square mile, run-off in inches, and acre-feet. They may be defined as follows:

"Second-feet" is an abbreviation for "cubic feet per second." A second-foot is the rate of discharge of water flowing in a channel of rectangular cross section 1 foot wide and 1 foot deep at an average velocity of 1 foot per second. It is generally used as a fundamental unit from which others are computed.

"Second-feet per square mile" is the average number of cubic feet of water flowing per second from each square mile of area drained, on the assumption that the run-off is distributed uniformly both as regards time and area.

"Run-off (depth in inches)" is the depth to which an area would be covered if all the water flowing from it in a given period were uniformly distributed on the surface. It is used for comparing run-off with rainfall, which is usually expressed in depth in inches.

An "acre-foot," equivalent to 43,560 cubic feet, is the quantity required to cover an acre to the depth of 1 foot. The term is commonly used in connection with storage for irrigation.

The following terms not in common use are here defined:

"Stage-discharge relation," an abbreviation for the term "relation of gage height to discharge."

"Control," a term used to designate the section or sections of the stream below the gage which determine the stage-discharge relation at the gage. It should be noted that the control may not be the same section or sections at all stages.

The "point of zero flow" for a given gaging station is that point on the gage—the gage height—to which the surface of the river would fall if there were no flow.

WATER-STAGE RECORDERS.

EXPLANATION OF DATA.

The data presented in this report cover the year beginning October 1, 1916, and ending September 30, 1917. At the beginning of January in most parts of the United States much of the precipitation in the preceding three months is stored as ground water in the form of snow or ice, or in ponds, lakes, and swamps, and this stored water passes off in the streams during the spring break-up. At the end of September, on the other hand, the only stored water available for run-off is possibly a small quantity in the ground; therefore the run-off for the year beginning October 1 is practically all derived from precipitation within that year.

The base data collected at gaging stations consist of records of stage, measurements of discharge, and general information used to supplement the gage heights and discharge measurements in determining the daily flow. The records of stage are obtained either from direct readings on a staff gage or from a water-stage recorder that gives a continuous record of the fluctuations. Measurements of discharge are made with a current meter. (See Pls. I, II.) The general methods are outlined in standard textbooks on the measurement of river discharge.

From the discharge measurements rating tables are prepared that give the discharge for any stage, and these rating tables, when applied to the gage heights, give the discharge from which the daily, monthly, and yearly mean discharge is determined.

The data presented for each gaging station in the area covered by this report comprise a description of the station, a table giving results of discharge measurements, a table showing the daily discharge of the stream, and a table of monthly and yearly discharge and run-off.

If the base data are insufficient to determine the daily discharge, tables giving daily gage heights and results of discharge measurements are published.

The description of the station gives, in addition to statements regarding location and equipment, information in regard to any conditions that may affect the constancy of the stage-discharge relation, covering such subjects as the occurrence of ice, the use of the stream for log driving, shifting of control, and the cause and effect of backwater. It gives also information as to diversions that decrease the flow at the gage, artificial regulation, maximum and minimum recorded stages, and the accuracy of the records.

The table of daily discharge gives, in general, the discharge in second-feet corresponding to the mean of the gage heights read each day. At stations on streams subject to sudden or rapid diurnal fluctuation the discharge obtained from the rating table and the mean daily gage height may not be the true mean discharge for the day. If such stations are equipped with water-stage recorders, the mean daily discharge may be obtained by averaging discharge at regular intervals during the day, or by using the discharge integrator, an instrument operating on the principle of the planimeter and containing as an essential element the rating curve of the station.

In the table of monthly discharge the column headed "Maximum" gives the mean flow for the day when the mean gage height was highest. As the gage height is the mean for the day, it does not indicate correctly the stage when the water surface was at crest height, and the corresponding discharge was consequently larger than given in the maximum column. Likewise, in the column headed "Minimum," the quantity given is the mean flow for the day when the mean gage height was lowest. The column headed "Mean" is the average flow in cubic feet for each second during the month. On this average flow computations recorded in the remaining columns, which are defined on page 8, are based.

ACCURACY OF FIELD DATA AND COMPUTED RESULTS.

The accuracy of stream-flow data depends primarily (1) on the permanence of the stage-discharge relation, and (2) on the accuracy of observation of stage measurements of flow, and interpretation of records.

A paragraph in the description of the station of footnotes added to the tables gives information regarding the (1) permanence of the stage-discharge relation, (2) precision with which the discharge rating curve is defined, (3) refinement of gage readings, (4) frequency of gage readings, and (5) methods of applying daily gage heights to the rating table to obtain the daily discharge.[1]

For the rating tables "well defined" indicates, in general, that the rating is probably accurate within 5 per cent; "fairly well defined," within 10 per cent; "poorly defined," within 15 to 25 per cent. These notes are very general and are based on the plotting of the individual measurements with reference to the mean rating curve.

The monthly means for any station may represent with high accuracy the quantity of water flowing past the gage, but the figures showing discharge per square mile and depth of run-off in inches may be subject to gross errors caused by the inclusion of large noncontributing districts in the measured drainage area, by lack of information concerning water diverted for irrigation or other use, or by inability to interpret the effect of artificial regulation of the flow of the river above the station. "Second-feet per square mile" and "Run-off (depth in inches)" are therefore not computed if such

[1] For a more detailed discussion of the accuracy of stream-flow data see Grover, N. C., and Hoyt, J. C.: Accuracy of stream-flow data: U. S. Geol. Survey Water-Supply Paper 400, pp. 53–59, 1916.

errors appear probable. The computations are also omitted for stations on streams draining areas in which the annual rainfall is less than 20 inches. All figures representing "second-feet per square mile" and "run-off (depth in inches)" previously published by the Survey should be used with caution because of possible inherent sources of error not known to the Survey.

The table of monthly discharge gives only a general idea of the flow at the station and should not be used for other than preliminary estimates. The tables of daily discharge allow more detailed studies of the variation in flow. It should be borne in mind, however, that the observations in each succeeding year may be expected to throw new light on data previously published.

COOPERATION.

Much of the work in Montana has been carried on under cooperative agreement with the United States Reclamation Service, the work being done by the Geological Survey and the expense borne by the Reclamation Service. The legislature of the State of Montana made an appropriation for stream-gaging work, which was expended by the State engineer, as provided in the act, in accordance with paragraph 3, section 2244, of the Revised Codes of 1907 of the State of Montana, which reads as follows:

> The State engineer shall become conversant with the waterways of the State and the needs of the State as to irrigation matters, shall make, or cause to be made, measurements and calculations of the ordinary and flood discharge of streams, cooperating in this work as much as possible with the United States Geological Survey and the Montana Experiment Station; such measurements to be made on streams in order of their importance, provided that measurements already made, if deemed reliable, may be adopted.

This fund was expended largely on work in connection with the several Carey projects in Montana and in computing data on water-right filings and adjudications. A State hydrographer was employed who worked directly with the Geological Survey.

The expense of work on the Crow Reservation in Montana, the Standing Rock Reservation in North and South Dakota, and the Pine Ridge and Rosebud Reservations in South Dakota was borne by the Office of Indian Affairs.

Officials of the Yellowstone National Park have furnished valuable hydrometric and climatic data and paid a large part of the expense of work in the park.

All stations in Wyoming were maintained in cooperation with the State, through Mr. J. B. True, State engineer.

The United States Reclamation Service paid for the maintenance of the stations on North Platte River above Pathfinder, Wyo., and on Sage Creek above Pathfinder.

The Laramie Water Co. furnished gage-height records for the following stations: Laramie River and Pioneer canal near Woods; Laramie River at Two Rivers; Laramie River near Lookout; Laramie River below McGill; and Little Laramie River at Two Rivers.

The Rock Creek Conservation Co., through Mr. Frank C. Bosler, furnished field data for stations on Rock and Deep creeks near Arlington, Wyo. The United States Forest Service furnished gage-height records for Big Creek near Big Creek. The Hawk Springs Development Co., through Mr. J. A. Whiting, furnished record of gage heights and provided transportation necessary to obtain data for the station on Horse Creek near La Grange, Wyo.

The L. Z. Leiter estate, through Mr. J. C. Beebe, manager, furnished gage-height records for station at Ucross, Wyo, and a number of discharge measurements at several stations. Gage-height records were also furnished as follows: The Buffalo Manufacturing Co., for Clear Creek near Buffalo; the Swan Land & Cattle Co., for Chugwater Creek at Chugwater; the Wyoming Irrigation Co. for Shell Creek at Shell, Wyo.

Messrs. Johnson and Cronberg furnished gage-height records and other assistance in connection with the station on Medicine Bow River near Medicine Bow, Wyo., and Mr. F. H. Richards assisted in like manner in obtaining the record at the station on Muddy Creek near Shirley.

Records were furnished by the State engineer of Colorado for Laramie River near Jelm, Wyo., and by the North Laramie Land Co. for North Laramie River near Wheatland, Wyo.

The Farmers' Reservoir & Irrigation Co. furnished the gage-height records and paid for the maintenance of the station on Clear Creek near Golden, Colo. The State engineer paid the gage observers at the following stations in Colorado: South Platte River at South Platte; North Fork of South Platte River at Grant and at South Platte; and Geneva Creek at Grant. The Tarryall Canal & Reservoir Co. paid the expense of maintaining the station on Tarryall Creek near Jefferson, Colo.

In South Dakota the State engineer, Dr. H. M. Derr, paid the observer's salary at the station on Cheyenne River near Hot Springs.

The stations in Kansas were maintained in cooperation with the Kansas Water Commission.

DIVISION OF WORK.

Data for stations in the upper Missouri River basin in Montana and North Dakota were collected and prepared for publication under the direction of W. A. Lamb, district engineer, who was assisted by E. F. Chandler, A. H. Tuttle, R. F. Edwards, and Lois H. Hershner, and by C. S. Heidel, State hydrographer for Montana.

Data relating to tributaries of Missouri River in Colorado, South Dakota, and Wyoming were collected and prepared for publication under the direction of Robert Follansbee, district engineer, who was assisted by S. B. Soulé, H. W. Fear, P. V. Hodges, H. K. Smith, and Miss Jane Hanna.

Data for two stations in the Yellowstone National Park were collected and prepared for publication under the direction of G. C. Baldwin, district engineer, who was assisted by C. G. Paulsen and E. Hazel Haugse.

Data for stations in Kansas were collected and prepared for publication by R. C. Rice, district engineer.

GAGING-STATION RECORDS.

MISSOURI RIVER PROPER.

RED ROCK CREEK BELOW RED ROCK RESERVOIR, NEAR MONIDA, MONT.

LOCATION.—In sec. 32, T. 13 S., R. 6 W., at weir 150 yards below reservoir of Red Rock Reservoir & Irrigation Co., 8 miles northeast of Monida and 15 miles east of Lima, in Beaverhead County.

DRAINAGE AREA.—560 square miles.

RECORDS AVAILABLE.—July 22, 1911, to September 30, 1917; also miscellaneous measurements made in summer of 1910.

GAGE.—Stage determined by measuring with graduated rod the depth on a peg in concrete well set with its top at elevation of crest of weir. Observations made by P. V. Maxwell. Float gage in concrete well used in 1912 and 1913. During 1911 a temporary vertical staff on left bank 300 yards below dam was read. Gage heights beginning with those for 1912 indicate head on crest of 40-foot weir 150 yards below dam.

DISCHARGE MEASUREMENTS.—Made from footbridge 40 feet above weir or by wading.

CHANNEL AND CONTROL.—Bed composed of coarse gravel, pebbles, and boulders. Banks high; right bank is subject to overflow only during extremely high water. Current so swift at high stages that channel above weir, if cleaned out, soon becomes partly filled with rocks and pebbles, which cause considerable velocity of approach. Stage-discharge relation seldom changes after natural deposit has been allowed to rest undisturbed.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 2.8 feet at 6 p. m. May 13 and 8 a. m. May 14 (discharge, 1,080 second-feet; minimum stage recorded, 0.66 foot August 28-31, and September 1-3 and 6-9 (discharge, 75 second-feet).

1911-1917: Maximum stage recorded, 3.2 feet April 28, 1914 (discharge, 1,220 second-feet); minimum stage recorded, 0.10 foot January 1 to April 10, 1913 (discharge, 5 second-feet).

ICE.—Stage-discharge seriously affected by ice; observations discontinued during winter.

DIVERSIONS.—None.

REGULATION.—Dam is used to store flood waters which are released as required during irrigating season.

ACCURACY.—Stage-discharge relation practically permanent both before and after weir was cleaned July 11–13, a change occurring at that time. Rating curve used to July 11 well defined between 200 and 500 second-feet; rating curve used after July 13 well defined. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating tables, except for July 11–13, when it was interpolated. Records good.

COOPERATION.—Record of daily gage height furnished by Red Rock Reservoir & Irrigation Co.

The following discharge measurement was made by C. S. Heidel:

October 5, 1916: Gage height, 1.20 feet; discharge, 230 second-feet.

Daily discharge, in second-feet, of Red Rock Creek below Red Rock reservoir, near Monida, Mont., for the year ending Sept. 30, 1917.

August	111	75	85.6	5,260
September	82	75	77.5	4,610

BEAVERHEAD RIVER AT BARRATTS, MONT.

LOCATION.—In SW. ¼ SW. ¼ sec. 20, T. 8 S., R. 9 W., at highway bridge at point where highway crosses railroad and where both highway and railroad bridges cross river, 1 mile above Barratts, in Beaverhead County, 2 miles below mouth of Grasshopper Creek, and 10 miles southwest of Dillon.

DRAINAGE.—Not measured.

RECORDS AVAILABLE.—August 12, 1907, to September 30, 1917.

GAGE.—Chain gage on downstream side of bridge; read twice daily by T. Masuno. Before June 22, 1908, a staff gage was used. Datum of chain gage same as that of staff gage.

DISCHARGE MEASUREMENTS.—Made from downstream side of bridge.

CHANNEL AND CONTROL.—Banks high, covered with brush, and not subject to overflow. Stream bed clean and rocky. Two channels at low and medium stages, caused by an old pier; sudden changes unlikely.

EXTREMES OF DISCHARGE.—Maximum stage recorded during the year, 5.70 feet at 7.45 a. m. May 16 (discharge, 3,200 second-feet); minimum stage 0.95 foot at 3.55 p. m. February 18 (discharge, 240 second-feet).

1907–1917: Maximum stage recorded, 6 feet June 19 and 20, 1908 (discharge, 3,640 second-feet); minimum stage recorded, 0.42 foot June 23, 1910 (discharge, 114 second-feet).

ICE.—Stage-discharge relation not affected by ice during 1917.

DIVERSIONS.—Numerous diversions are made above station. Water rights aggregating 85,866 inches of water are decreed from Lima on Red Rock Creek to a point 10 miles above Twin Bridges. The three largest canals diverting below the station are Canyon Creek canal, appropriating 6,000 inches; Union canal, appropriating 4,000 inches; and Beaverhead canal, diverting just north of Dillon, appropriating 5,000 inches. Union Electric Co. of Dillon has a canal with a carrying capacity of 6,000 inches.

REGULATION.—Operation of the dam on Red Rock Creek near Monida, used to store flood waters, has some effect on the flow at this station.

ACCURACY.—Stage-discharge relation not affected by ice or shifting control during year. Rating curve fairly well defined between 400 and 2,200 second-feet. Gage read to half-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records good.

Beaverhead River is called Red Rock Creek from its source in Red Rock Lakes to Red Rock post office, below which it is called the Beaverhead. Principal tributaries of Beaverhead River above station are Grasshopper Creek, 12 miles south of Dillon; Horse Prairie Creek, 20 miles south; and Rattlesnake and Blacktail Deer creeks. Irrigation has probably been practiced in Beaverhead Valley longer than in any other valley in Montana, because ditches constructed in the early seventies are still in operation.

The following discharge measurement was made by C. S. Heidel:

October 3, 1916: Gage height, 1.65 feet; discharge, 532 second-feet.

Daily discharge, in second-feet, of Beaverhead River at Barratts, Mont., for the year ending Sept. 30, 1917.

MISSOURI RIVER AT FORT BENTON, MONT.

Location.—In NE. ¼ sec. 26, T. 24 N., R. 8 E., on highway bridge at Fort Benton, Choteau County.

Drainage area.—24,600 square miles.

Records available.—July 1, 1902, to April 27, 1910, gage heights recorded by United States Weather Bureau; April 28, 1910, to September 30, 1917, United States Geological Survey records.

Gage.—Chain gage on upstream side of bridge installed July 30, 1917. Mott gage read April 11, 1907, to July 30, 1917. Gage heights for 1911–1917 are referred to datum used by United States Army Engineers from 1880–1890, which is 0.43 foot higher than that used by United States Geological Survey in 1910.

Channel and control.—Channel composed of coarse gravel and sand. Control is rock ledge covered with heavy boulders, located 1,000 feet below gage; may shift slightly.

Extremes of discharge.—Maximum stage recorded during year, 9.90 feet at 9 a. m. May 27 (discharge, 55,200 second-feet); minimum stage recorded, 0.36 foot, August 26 (discharge, 3,650 second-feet).

1881–1917: Maximum stage recorded, 9.90 feet May 27, 1917 (discharge, 55,200 second-feet); maximum stage recorded by United States Weather Bureau, 15.3 feet June 7, 1908 (discharge not computed); minimum open-water stage recorded, −0.2 foot September 10, 1914 (discharge, 2,250 second-feet); minimum stage recorded by United States Weather Bureau, −0.5 foot August 7–10, 17, and 18, 1910 (discharge not computed). Open-season records only; flow may have been lower during winter.

Ice.—Stage-discharge relation seriously affected by ice; December 13 to March 20, flow not computed.

Diversions.—Numerous diversions from tributaries.

Regulation.—Flow partly regulated by operation of storage reservoirs and power plants of Montana Power Co. above station.

Accuracy.—Stage-discharge relation affected by ice December 13 to March 21; otherwise permanent. Rating curve well defined above 2,050 second-feet. Gage read to hundredths twice daily; readings July 1–19 unreliable and were not used. Daily discharge ascertained by applying mean daily gage height to rating table. Records only fair October 14 to July 19 on account of trouble with Mott gage; good after July 20.

Discharge measurements of Missouri River at Fort Benton, Mont., during the year ending Sept. 30, 1917.

31	6,700			18,000		52,400		6,000	3,750	

NOTE.—Stage-discharge relation seriously affected by ice; flow not computed Dec. 13 to Mar. 20, although gage-height record is continuous for period. No readings Oct. 1-13; flow not computed. Gage-height records July 1-19 discarded owing to errors in observer's readings; discharge interpolated for period.

Monthly discharge of Missouri River at Fort Benton, Mont., for the year ending Sept. 30, 1917.

MADISON RIVER BASIN.

MADISON RIVER NEAR YELLOWSTONE, MONT.

LOCATION.—Approximately in sec. 5, T. 14 S., R. 6 E. Montana meridian, 250 feet downstream from old footbridge at fording place of old Gallatin trail 300 feet north of stage road to Yellowstone, almost directly in front of Riverside soldier station, and 4 miles east of Yellowstone and west boundary of Yellowstone National Park. Gibbon and Firehole rivers unite to form the Madison 8 miles upstream.

DRAINAGE AREA.—410 square miles (measured on topographic maps).

RECORDS AVAILABLE.—June 16, 1913, to September 30, 1917.

GAGE.—Vertical staff on left bank; read by Chas. A. Smith and other soldiers attached to Riverside soldier station.

DISCHARGE MEASUREMENTS.—High-stage measurements made from cable one-third mile below gage, installed September 9, 1917. Previous to this date high-stage measurements made from old footbridge 250 feet upstream from gage. Medium and low stage measurements made by wading at gage.

CHANNEL AND CONTROL.—One channel at all stages. Bed of stream is gravel and boulders; somewhat rough; control is probably permanent. Aquatic growth is present during greater part of year and during summer affects the stage-discharge relation.

ICE.—Stage-discharge relation not seriously affected by ice. Temperature of water except during extremely cold weather kept above freezing point by numerous hot springs and geysers.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 2.64 feet at 6 p. m. June 10 (discharge, 1,950 second-feet); minimum stage recorded 1.30 feet at 4 p. m., January 22 (discharge, 420 second-feet).

1913–1917: Maximum stage recorded, 2.64 feet at 6 p. m. June 10, 1917 (discharge, 1,950 second-feet); minimum stage recorded, 1.25 feet July 21–25, 1915 (discharge, 370 second-feet).

DIVERSIONS.—None above station.

REGULATION.—None.

ACCURACY.—Stage-discharge relation practically constant during year, except during August and September, when it was affected by aquatic growth. Two fairly well defined rating curves used, one applicable October 1 to July 31; the other August 17 to September 30. Shifting-control methods used August 1–16. Gage read to half-tenths once daily. Daily discharge ascertained by applying daily gage height to rating table. Records only fair, chiefly on account of unstable condition of gage during most of the year.

Discharge measurements of Madison River near Yellowstone, Mont., during the year ending Sept. 30, 1917.

[Made by G. C. Baldwin.]

PRICKLY PEAR CREEK BASIN.

TENMILE CREEK NEAR RIMINI, MONT.

LOCATION.—In NE. ¼ sec. 20, T. 9 N., R. 5 W., opposite Moose Creek ranger station, 500 feet above mouth of Moose Creek, and 3 miles north of Rimini, in Lewis and Clark County.

DRAINAGE AREA.—Not measured.

RECORDS AVAILABLE.—March 13, 1915, to September 30, 1917.

GAGE.—Friez water-stage recorder on left bank opposite ranger station; observer, D. H. Lewis, a forest ranger.

DISCHARGE MEASUREMENTS.—Made by wading just below gage.

CONTROL.—Gravel and boulders; slightly shifting. Left bank high and steep; composed of loose material; will not be overflowed but will erode. Right bank sloping and subject to overflow.

EXTREMES OF DISCHARGE.—Maximum stage recorded during the year, 4.87 feet at 2 p. m., May 15 (discharge, 948 second-feet); minimum stage recorded, 1.28 feet at 6 p. m., October 10, 1916 (discharge, 1.4 second-feet).

1915–1917: Maximum stage recorded, 4.87 feet at 2 p. m., May 15, 1917 (discharge, 948 second-feet); minimum stage, 1.28 feet at 6 p. m., October 10, 1916 (discharge, 1.4 second-feet).

ICE.—Stage-discharge relation affected very little, if any, by ice; open-channel conditions assumed.

DIVERSIONS.—Small ditch diverts in summer for water supply of Helena.

REGULATION.—Small reservoir of water supply system of Helena is above station, but operation of reservoir has probably little, if any, effect upon the flow past gaging station.

ACCURACY.—Stage-discharge relation changed during year. Fairly well defined rating curves used for short periods. Water-stage recorder did not operate satisfactorily, except for short periods in October, November, April, and May. After January 2 staff gage was read to hundredths once daily, except for periods indicated in footnote to daily-discharge table. Daily discharge ascertained by applying to rating table mean daily gage height determined from recorder graph, or daily reading from staff gage. Records fair.

Discharge measurements of Tenmile Creek near Rimini, Mont., during the year ending Sept. 30, 1917.

TENMILE CREEK NEAR HELENA, MONT.

LOCATION.—In SW. ¼ SE. ¼ sec. 22, T. 10 N., R. 4 W., opposite Broadwater Hotel, near Helena, in Lewis and Clark County.

DRAINAGE AREA.—Not measured.

RECORDS AVAILABLE.—July 8, 1908, to September 30, 1917.

GAGE.—Staff on right bank; read by J. W. Jackson.

DISCHARGE MEASUREMENTS.—Made by wading, or from highway bridge 500 feet below gage.

CHANNEL AND CONTROL.—Bed of stream composed of coarse gravel and boulders; shifting occasionally.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 5.60 feet at 6.30 p. m. May 28 (discharge, 865 second-feet); minimum stage recorded, 1.75 feet August 24–28 (discharge, 2.3 second-feet).

1908–1917: Maximum stage recorded, 5.60 feet at 6.30 p. m. May 28, 1917 (discharge, 865 second-feet); minimum stage recorded, 1.15 feet August 5 to September 10, 1910 (discharge, 0.15 second-foot).

ICE.—Stage-discharge relation slightly affected by ice. For flow during period, see note to table of daily discharge.

DIVERSIONS.—Part of water supply for city of Helena is taken from Tenmile Creek above station. Two irrigation ditches also take water from the creek above gage. The entire low-water flow is appropriated and used before it reaches the mouth of the creek.

REGULATION.—None.

ACCURACY.—Stage-discharge relation affected by shifting control; very little, if any, by ice effect. Rating curve used October 1 to May 31 fairly well defined between 10 and 700 second-feet; indirect method used June 1 to September 30. Gage read to half-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records good October to December and March 15 to May 31; fair for rest of year.

Discharge measurements of Tenmile Creek, near Helena, Mont., during the year ending Sept. 30, 1917.

LITTLE PRICKLY PEAR CREEK BASIN.

LITTLE PRICKLY PEAR CREEK NEAR MARYSVILLE, MONT.

LOCATION.—At highway bridge on ranch of Casper Traufer, about a quarter of a mile below mouth of Deadman Creek and 6 miles northwest of Marysville, in Lewis and Clark County.

DRAINAGE AREA.—49 square miles (measured on topographic map).

RECORDS AVAILABLE.—May 24, 1913, to September 30, 1917, at present site; April 12, to May 23, 1913, a quarter of a mile above present site; May 18, 1909, to December 31, 1911, at station formerly maintained above mouth of Deadman Creek.

GAGE.—Vertical staff spiked to upstream side of left abutment of highway bridge; read by Casper Traufer. April 12 to May 23, 1913, vertical staff a quarter of a mile above present site; washed out by high water and replaced by present gage at different datum; discharge practically the same at the two points. Gage used May 18, 1909, to December 31, 1911, was a vertical staff on downstream side of Mr. Pearce's private bridge, half a mile above mouth of Deadman Creek.

DISCHARGE MEASUREMENTS.—Made from bridge or by wading at bridge.

CHANNEL AND CONTROL.—Sand and gravel; shifts slightly.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 3.8 feet May 25 and 26 (discharge, 454 second-feet); minimum discharge, 7.5 second-feet, September 23 and 24.

1909–1911 and 1913–1917: Maximum stage recorded, 3.8 feet May 25 and 26, 1917 (discharge, 454 second-feet); minimum stage, 2.28 feet (old gage) March 7–13, 1911 (discharge, 1.2 second-feet).

ICE.—Stage-discharge relation seriously affected by ice; observations discontinued during winter.

DIVERSIONS.—Numerous small ditches divert water from the stream, practically the entire normal flow being appropriated.

REGULATION.—None.

ACCURACY.—Stage-discharge relation not permanent; affected by shifting control and occasionally by ice. Rating curve used October 1 to June 10 well defined between 15 and 340 second-feet; curve used July 28 to September 30 poorly defined; shifting-control method used June 11 to July 27. Gage read to half-tenths twice daily. Daily discharge obtained by applying mean daily gage height to rating table.

Discharge measurements of Little Prickly Pear Creek near Marysville, Mont., during the year ending Sept. 30, 1917.

LITTLE PRICKLY PEAR CREEK NEAR CANYON CREEK, MONT.

Location.—In NW. ¼ sec. 9, T. 12 N., R. 5 W., near ford on Carbis ranch, below mouth of Canyon Creek, and 1¼ miles from Canyon Creek post office, in Lewis and Clark County.

Drainage area.—180 square miles (measured on topographic map).

Records available.—April 1, 1909, to December 31, 1911; and April 12, 1913, to September 30, 1917.

Gage.—Vertical staff attached to tree on right bank about 40 feet above ford; gage installed June 2, 1917, at independent datum, to replace the one washed out May 13; read by Melville Carbis.

Discharge measurements.—Made by wading near gage, or from wagon bridge 300 feet above gage.

Channel and control.—Sand and gravel; shifting. Banks overgrown with brush.

Extremes of discharge.—Maximum discharge recorded during year, 534 second-feet June 3–5; minimum stage, 0.50 foot July 28–31 and August 3–5 (discharge, 6.5 second-feet).

1909–1911 and 1913–1917: Maximum stage recorded, 4.8 feet May 29, 1913 (discharge, 665 second-feet); creek reported dry June 21–28, July 1–9, 21–22, August 1–2, 1910; July 22–27, 29, and 31, 1911.

Ice.—Stage-discharge relation seriously affected by ice; observations discontinued during winter.

Diversions.—Many small ditches divert from the stream; low-water flow practically all appropriated.

Regulation.—None.

Accuracy.—Stage-discharge relation permanent during year but a change of datum was made June 2 when new gage was installed. Rating curve well defined between 10 and 350 second-feet. Records good.

Discharge measurements of Little Prickly Pear Creek near Canyon Creek, Mont., during the year ending Sept. 30, 1917.

SUN RIVER BASIN.

NORTH FORK OF SUN RIVER NEAR AUGUSTA, MONT.

Location.—In sec. 36, T. 22 N., R. 9 W. (unsurveyed), at Sun River diversion dam, 18 miles northwest of Augusta, in Lewis and Clark County.

Drainage area.—Not measured.

Records available.—January 1, 1916, to September 30, 1917, at present site. From August 5, 1889, to December 31, 1890, and October 31, 1903, to December 31, 1915, a station in sec. 33, T. 22 N., R. 7 W., at the Henningson ranch, 8 miles downstream from present site. The flow is practically the same at both points, there being no large intervening tributaries entering and no diversions.

GAGE.—A sloping staff gage on right abutment of the Sun River diversion dam; read twice daily by employees of United States Reclamation Service. From October 31, 1903, to December 31, 1915, an overhanging chain gage was on left bank below ranch buildings of the Henningson Co. From August 5, 1889, to December 31, 1890, the gage was also near this point.

DISCHARGE MEASUREMENTS.—Made from footbridge at siphon half a mile below gage.

CHANNEL AND CONTROL.—Control is crest of Sun River diversion dam—a concrete structure with an arch section 153.3 feet long, and a gravity section 59.2 feet long, separated by a pier.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 8.2 feet at 6 p. m. May 25 (discharge, 18,700 second-feet); minimum stage recorded, 0.23 foot April 2 (discharge, 64 second-feet).

ICE.—Stage-discharge relation not affected by ice during year.

DIVERSIONS.—None.

REGULATION.—None.

ACCURACY.—Stage-discharge relation permanent. Rating curve well defined. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records good.

The following discharge measurement was made by W. A. Lamb:

May 13, 1917: Gage height, 2.92 feet; discharge, 3,380 second-feet.

Daily discharge, in second-feet, of North Fork of Sun River near Augusta, Mont., for the year ending Sept. 30, 1917.

SUN RIVER AT FORT SHAW, MONT.

LOCATION.—In SW. ¼ sec. 1, T. 20 N., R. 2 W., at highway bridge at Fort Shaw, Cascade County.

DRAINAGE AREA.—Not measured.

RECORDS AVAILABLE.—May 16, 1912, to September 30, 1917, A station on Sun River at Sun River, maintained July 31, 1905, to December 31, 1912, gave records for practically the same drainage area.

GAGE.—Chain gage at highway bridge read since November 24, 1916, by C. G. Peterson, an employee of the United States Reclamation Service; stage prior to September 1, 1913, measured by standard chain gage fastened to footbridge near right bank and 1,000 feet downstream. Staff gage September 1, 1913, to November 23, 1916, on right bank 400 feet above highway bridge. The three gages referred to different datums.

DISCHARGE MEASUREMENTS.—Made from highway bridge or by wading.

CHANNEL AND CONTROL.—Bed composed of gravel and rock; fairly permanent; shifting only at extremely high stages.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 13.3 feet at 10.15 a. m. May 26 (discharge, 17,600 second-feet); minimum stage recorded, 4.70 feet December 5 (discharge, 265 second-feet); lower minimum probably occurred during frozen season.

1905–1917: Maximum stage recorded, 13.4 feet June 7, 1908 (discharge, 18,400 second-feet); minimum stage recorded at Sun River, 1.3 feet September 14, 1906 (discharge, 47 second-feet); at Fort Shaw, 1.65 feet August 5, 6, and 8, 1914 (discharge, 95 second-feet). The high-stage discharge at Fort Shaw and Sun River is practically the same but at low stages the operation of Sun River canal (capacity about 50 second-feet), which takes out between the stations, may cause a material difference.

ICE.—Stage-discharge relation affected by ice November 12–18, 28, and December 5. Flow estimated for first period, and interpolated for others. Gage-height record continuous but discharge not computed December 10 to March 31.

DIVERSIONS.—Adjudicated rights for diverting 248 second-feet from Sun River direct and 664 second-feet from tributaries above this station. In addition, the Fort Shaw canal of the United States Reclamation Service takes out about 200 second-feet during irrigation season.

REGULATION.—Willow Creek reservior has a capacity of 84,200 acre-feet.

ACCURACY.—Rating curve well defined below 1,500 second-feet; used October 1 to December 9, except during ice-affected period. Curve fairly well defined between 470 and 8,760 second-feet; used April 1 to September 30. Gage read to half-tenths twice daily. Daily discharge obtained by applying mean daily gage height to rating table. Open-water records good; records for periods of ice effect fair.

Discharge measurements of Sun River at Fort Shaw, Mont., during the year ending Sept. 30, 1917.

[Made by W. A. Lamb.]

WILLOW CREEK NEAR AUGUSTA, MONT.

LOCATION.—In NW. ¼ SW. ¼ sec. 26, T. 21 N., R. 7 W., at Clark Co.'s ranch, just below mouth of Little Willow Creek and 7 miles northwest of Augusta, in Lewis and Clark County.

DRAINAGE AREA.—Not measured.

RECORDS AVAILABLE.—June 8, 1905, to May 14, 1911; April 1, 1912, to September 30, 1917.

GAGE.—Chain gage on right bank, 300 feet back of Thomas Clark's house; read by Thomas Clark.

DISCHARGE MEASUREMENTS.—Made by wading or from bridge 1,000 feet below gage.

CHANNEL AND CONTROL.—An old dam of timber and rock 20 feet below gage forms the principal control; shifts slightly at long intervals.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 5.88 feet June 5 (discharge, 390 second-feet); water over gage May 25 to June 4 (discharge not determined); minimum (discharge, 13 second-feet) February 23 to March 5 and March 18-25.

1905-1917: Maximum stage recorded, 10.8 feet June 23, 1916 (discharge, 1,150 second-feet); minimum stage, dry July 17, 1910.

ICE.—Probably no ice forms at this station, as a large spring enters the creek just above gage, but winter flow should be used with caution.

DIVERSIONS.—Adjudicated water rights above station amount to 36.2 second-feet from Willow Creek and 42.26 second-feet from tributaries. The United States Reclamation Service has an old right of 2.1 second-feet and has also filed on the total flow of the creek, subject to prior appropriations. No water diverted from Willow Creek proper below station, the amount used by the United States Reclamation Service being diverted from Sun River below mouth of Willow Creek.

REGULATIONS.—None. Willow Creek dam, 2 miles below station, forms a reservoir with a capacity of 84,320 acre-feet, for use on Fort Shaw unit of Sun River project. In addition to flow of Willow Creek, water will be diverted from North Fork of Sun River for storage in this reservoir.

ACCURACY.—Stage-discharge relation not permanent; affected by occasional shifts of control, usually at high stage. Rating curve used October 1 to November 15 and March 28 to May 24 well defined between 25 and 700 second-feet; curve used June 5 to September 30 fairly well defined between 20 and 250 second-feet. Gage read to half-tenths once daily; occasionally twice daily. Daily discharge ascertained by applying daily gage height to rating table. Records fair.

Discharge measurements of Willow Creek near Augusta, Mont., during the year ending Sept. 30, 1917.

MARIAS RIVER BASIN.

TWO MEDICINE RIVER AT FAMILY, MONT.

LOCATION.—In NE. ¼ sec. 2, T. 31 N., R. 9 W., at Holy Family Mission, in Teton County, 16 miles southeast of Browning and 6 miles above mouth of Badger Creek, the nearest tributary.

DRAINAGE AREA.—368 square miles.

RECORDS AVAILABLE.—April, 1907, to September 30, 1917.

GAGE.—Overhanging chain gage installed July 15, 1916, on left bank about 150 feet below barn belonging to Holy Family Mission; read twice daily by John Gobert. Temporary staff gage used May 4 to July 7, 1917, on account of high water. Datum of original gage, which was at same site as present gage, was lowered 0.95 foot July 21, 1908. Original chain gage and bench marks were destroyed by flood of June 2, 1913, and on June 10 a staff gage was installed at a different datum on left bank about 125 feet above site of chain gage. On July 23, 1913, this staff gage was removed to site of chain gage and was set to read 1.85 feet higher than staff gage installed June 10. Overhanging chain gage, installed September 18, 1913, was set to read 1 foot higher than staff gage installed July 23, 1913, and read to May 7, 1916, when destroyed by flood. Temporary gages at independent datum read May 16 to July 15, 1916, when present gage was installed.

DISCHARGE MEASUREMENTS.—Made by wading near gage or from old wagon bridge 3 miles above mission.

CHANNEL AND CONTROL.—Composed of gravel; shifting. Banks high and not subject to overflow except at extreme floods.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 7.65 feet June 8 (discharge 5,020 second-feet); minimum stage recorded, 2.50 feet August 23-25, September 14-16, 18, 20 (discharge, 24 second-feet).

1907-1917: Maximum stage recorded, 8.15 feet June 9, 1909 (discharge, 7,600 second-feet); undoubtedly higher in June, 1908, but no record available, as gage was washed out; minimum stage recorded, 1.3 feet January 12 to March 8, 1908 (discharge, 17 second-feet).

ICE.—Stage-discharge relation seriously affected by ice. Gage-height record continuous; flow estimated January 1, 11, 12, 19, 21-23, 28-31, February 1, 2, 18-28, March 1-5.

DIVERSIONS.—Water diverted about 2 miles above gage by ditch which supplies 100 acres on farm at the Holy Family Mission. From May 14 to October 24, a total diversion of 13,500 acre-feet was made by the United States Reclamation Service above the station to irrigate lands near Seville on the Blackfeet Indian Reservation.

REGULATION.—None.

ACCURACY.—Stage-discharge relation changed by high water occurring in May and June. Rating curve used until May 10, fairly well defined below 1,100 second-feet; curve used May 11 to September 30 well defined between 20 and 3,200 second-feet. Gage read twice daily to hundredths. Gage heights apparently in error and discharge estimated July 2-8; discharge interpolated July 18 and 19. Records good.

Discharge measurements of Two Medicine River near Family, Mont., during the year ending Sept. 30, 1917.

MARIAS RIVER NEAR SHELBY, MONT.

Location.—In sec. 20, T. 31 N., R. 2 W., at highway bridge near James A. Johnson's ranch, 7 miles south of Shelby, in Toole County.

Drainage area.—2,610 square miles.

Records available.—April 4, 1902, to January 12, 1908; April 23, 1911, to September 30, 1917.

Gage.—Chain gage on downstream side of bridge. April 4, 1902, to January 12, 1908, chain gage on highway bridge, 100 feet below present bridge; during 1911 and 1912 Bristol water-stage recorder; all gages at practically the same datum. Gage read by G. J. Moser to November 18, 1916, and by Emma Moser April 4, to September 30.

Discharge measurements.—Made from downstream side of highway bridge.

Channel and control.—Bed composed of gravel and boulders; control shifts. Left bank steep and high; not subject to overflow. Right bank gently sloping; subject to overflow at extreme stages.

Extremes of discharge.—Maximum stage recorded during year 8.4 feet May 31 (discharge, 10,000 second-feet); minimum stage recorded, 2.4 feet September 17-21 (discharge, 274 second-feet).

1902–1907 and 1911–1917: Maximum stage recorded, 14.9 feet June 24, 1907 (discharge, 29,500 second-feet); minimum stage recorded, 1.7 feet November 16–20, 1904 (discharge, 150 second-feet).

Ice.—Stage-discharge relation affected by ice November 15–18 and April 4–6; observations discontinued November 19 to April 3.

Diversions.—The Valier-Montana Land & Water Co.'s Carey project and the Blackfeet project of United States Reclamation Service divert water above this station; also a number of smaller private diversions.

Regulation.—None.

Accuracy.—Stage-discharge relation not permanent; affected by shift of control and by ice. Rating curve used October 1 to November 14 fairly well defined; shifting-control method used April 7 to May 31; curve used June 1 to September 30 well defined between 350 and 10,000 second-feet. Gage read to tenths (occasionally to half-tenths) once daily. Daily discharge ascertained by applying daily gage height to rating table. Records October 1 to November 14, fair; April 7 to May 31, poor; June 1 to September 30, good.

Discharge measurements of Marias River near Shelby, Mont., during the year ending Sept. 30, 1917.

BADGER CREEK NEAR FAMILY, MONT.

LOCATION.—In NE. ¼ sec. 19, T. 31 N., R. 8 W., near road crossing 4 miles east of Family, in Teton County.

DRAINAGE AREA.—241 square miles (revised); measured on topographic maps.

RECORDS AVAILABLE.—April 20, 1907, to September 30, 1917.

GAGE.—Chain gage read October 1–31, 1916, by O. J. Racine, and June 1, to September 30, by Joe Trombley. April 1, to May 31, by Aaron Racine. The original staff gage established April 20, 1907, and bench marks were washed out in the flood of June, 1908. New chain gage was established July 22, 1908, 400 feet farther upstream at a different datum. This gage was washed out May 25, 1909, and a new gage reset at different datum on the right bank, 400 feet below the old Piegan Mission crossing.

DISCHARGE MEASUREMENTS.—Made from a cable 4 miles above the gage or by wading at ford.

CHANNEL AND CONTROL.—Shifting; two channels at medium and low stages; several channels at high stage. Banks low and subject to overflow above gage.

EXTREMES OF DISCHARGE.—Maximum stage recorded during the year, 6.30 feet at 9 a. m., June 12 (discharge, 1,910 second-feet); minimum stage recorded, 4.15 feet at 6 p. m., April 18 (discharge, 122 second-feet).

1907–1917: Maximum stage recorded is that of June 12, 1917; minimum stage recorded, 3.45 feet September 25, 28, 30, 1914 (discharge, 92 second-feet); records for open-water season only; mean discharge for February, 1911, estimated at 25 second-feet.

ICE.—Observations discontinued during winter.

DIVERSIONS.—United States Reclamation Services proposes to divert the natural flow of Badger Creek to irrigate land in the eastern part of Blackfeet Indian Reservation north of Birch Creek. A small amount of water was diverted in 1917 above gage.

REGULATION.—None.

ACCURACY.—Stage-discharge relation changed June 10–19. Gage heights October 1-31 are the mean of two readings daily to half-tenths; June 1 to September 30 are the mean of two readings daily to nearest tenth. Records considered fair. Daily discharge October 1–31, April 14–20, and May 30 to June 9 are determined from a rating curve well defined between 160 and 1,600 second-feet; June 10–19 determined by indirect method for shifting control; June 20 to September 30 determined from a rating curve well defined between 140 and 800 second-feet. Records good after June 20; previous to that, fair.

Discharge measurements of Badger Creek near Family, Mont., during the year ending Sept. 30, 1917.

[Made by W. A. Lamb.]

BIRCH CREEK AT SWIFT DAM, NEAR DUPUYER, MONT.

Location.—At Swift dam, on south boundary of Blackfeet Indian Reservation, Teton County, 20 miles west of Dupuyer and 34 miles west of Valier. North and South forks of Birch Creek unite in reservoir above station.

Drainage area.—120 square miles.

Records available.—March 26, 1913, to September 30, 1917.

Gage.—Vertical iron gage on right bank 800 feet below dam, read by Herbert C. Stalzer. Prior to July 11, 1915, a vertical wooden staff on right bank a quarter of a mile below dam was read, except June 5 to July 16, 1913, when a temporary gage on left bank immediately below dam was used to obtain high-water records. Gage for spillway overflow is inclined staff attached to left wall of the concrete canal which carries the overflow away from spillway.

Discharge measurements.—Discharge through valves measured from footbridge 300 feet above gage or by wading near gage. The spillway overflow is measured from a footbridge or by wading on crest of spillway.

Channel and control.—Stream bed clean, coarse gravel and boulders. Banks at gage high; not subject to overflow, but at old gage site 500 feet below may be overflowed at extreme stages. Canal from spillway has concrete lining not subject to shifts.

Extremes of discharge—Maximum combined flow through gates and over spillway occurred on June 17 (total discharge, 1,180 second-feet); minimum flow estimated at 1 second-foot February 14–29, March 28 to April 21.

1913–1917: Maximum discharge, 5,275 second-feet at 5 a. m. June 21, 1916; minimum discharge, 0.9 second-foot March 6, 1915. Minimum flow is controlled and maximum partly regulated by valves at dam.

Ice.—Stage-discharge relation seriously affected by ice January 18–23 and February 1 to March 27. Discharge interpolated January 18–23; February 1–5 by interpolation from measurements January 31 and February 6; February 7–13, estimated. Gates closed February 14–28. Flow estimated 1 second-foot daily. March 1–27 flow estimated by observer from gate openings on following dates and discharge computed accordingly: March 1, 20 second-feet; March 4, 20 second-feet; March 14, 60 second-feet; March 22, 40 second-feet.

Diversions.—Two small ditches divert water just below dam and above gage.

Regulation.—Dam is used to store flood and winter flow, and during dry periods will release no more water than can be handled by the canal system of the Valier Carey project in addition to amount required by prior rights. Acre-feet in storage at end of each month was as follows: October, 2,760; November, 0; December, 0; January, 0; February, 1,940; March, 3,065; April, 6,092; May, 18,610; June, 29,750; July, 21,790; August, 8,080; September, 0.

Determination of discharge.—Flow through gates in dam passes down main channel past gage; flow over spillway passes down an artificial channel and joins creek about a quarter of a mile below dam and below gage. Gage heights indicate flow through gates not diverted between dam and gage. Flow over spillway computed from gage heights by observer by applying same to rating table for short periods of each day and mean discharge for 24 hours computed. Total mean daily flow from reservoir is obtained by adding mean daily discharge from spillway to mean daily flow past gage. Spillway overflowed June 16 to July 3.

Accuracy.—Stage-discharge relation permanent for both gages. Rating curve used October 1 to June 1 for gage in channel conveying flow from valves well defined; shifting control method used June 2 to September 30. Rating curve for gage in spillway fairly well defined below 3,000 second-feet, and roughly approximate above 3,000 second-feet. Gage in channel from valves read twice daily to hundredths. Gage in spillway channel read several times daily June 16–23 and 30 and once daily June 24–29 and July 1–3; no flow over spillway during rest of year. Comparison of records for this station with those for Birch Creek near Dupuyer indicates that one or the other is in error June 1 to August 31.

Cooperation.—All field data furnished by the engineering department of the Valier-Montana Land & Water Co.; computations made by United States Geological Survey.

The year	1,180	....	233	168,000

NOTE.—The above table shows total flow through valves and over spillway. Minimum flow of February, March, and April estimated at 1 second-foot, and represent leakage through gates which were closed during parts of these months.

BIRCH CREEK NEAR DUPUYER, MONT.

LOCATION.—In sec. 28, T. 29 N., R. 8 W., at Kepple's ranch, half a mile above head gates of B canal of Valier-Montana Land & Water Co., 12 miles northwest of Dupuyer, Teton County, and 20 miles above mouth of Dupuyer Creek.

DRAINAGE AREA.—155 square miles (measured on Land Office map).

RECORDS AVAILABLE.—July 25, 1907, to September 30, 1917.

GAGE.—Vertical 1-inch square steel bar marked to tenths located same as previous one; was replaced July 5, 1916, and referred to approximately the same datum as the previous gages at this location. May 12 a high-water staff gage was set at this same section but was not used. Low-water section was washed out June 18 and a new one installed on June 19, which was loose and unsatisfactory until June 30, when it was set to correct datum and securely fastened. June 23–30 the old sloping gage was read. Gage read by John Ryan.

A chain gage on right bank about 250 feet below inclined staff was used July 25, 1907, until June, 1908, when it was washed out. A temporary staff 200 feet below old chain gage was used July 23 to October 1, 1908, when a new chain gage was installed on right bank a quarter of a mile above old site. Chain gage used until December 31, 1913. Inclined staff read with datum unchanged January 1, 1914, to December 31, 1915. There is no relation determined between gage datums for the different sections. January 1, 1916, a vertical 1-inch square steel bar marked to tenths and located about 1,000 feet downstream was used. This was washed out June 21, 1916; observer set temporary gage at same location June 23 and it was read until July 5, 1916.

DISCHARGE MEASUREMENTS.—Made by wading or from cable. Cable originally 100 feet below inclined gage, but was moved downstream to 75 feet below new vertical steel staff; washed out June 21, 1916, and replaced May 7, 1917, at original site.

CHANNEL AND CONTROL.—Rock and gravel at inclined gage; principal control is riffle about 100 feet below; shifting. Large clean gravel at new gage section; control is gravel bar about 250 feet below gage. Banks at both sections are of medium height covered with brush and subject to overflow.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 6.62 feet June 17 (discharge, 1.080 second-feet); minimum stage recorded, 3.66 feet April 19 (discharge, 28 second-feet). A lower stage may have been reached during the winter period.

1907–1917: Maximum stage recorded, 10.0 feet June 21, 1916 (discharge estimated, 5,000 second-feet); minimum stage recorded April 21–30, 1915 (discharge 7 second-feet.)

ICE.—Stage-discharge relation seriously affected by ice; data inadequate to warrant estimates of flow December 12 to April 6.

DIVERSIONS.—Two or three small ditches divert above station.

REGULATION.—The flow is largely controlled by Swift dam at the Birch Creek reservoir with a storage capacity of 30,000 acre-feet, 12 miles upstream from station.

ACCURACY.—Stage-discharge relation affected by shifting control. Rating curve used October 1 to June 20 well defined between 20 and 1,000 second-feet; curve used June 21-30 based on gage heights of inclined gage, fairly well defined between 600 and 850 second-feet; July 1, to September 30 well defined between 80 and 750 second-feet. Gage read to hundredths once daily. Daily discharge obtained by applying daily gage height to rating table. Records fair.

COOPERATION.—Gage heights and most of discharge measurements furnished by engineering department of Valier-Montana Land & Water Co.

Discharge measurements of Birch Creek near Dupuyer, Mont., during the year ending Sept. 30, 1917.

BIRCH CREEK AT NELSON'S RANCH, NEAR DUPUYER, MONT.

LOCATION.—In NW. ¼ sec. 27, T. 29 N., R. 8 W., a quarter of a mile below headworks of B canal of Valier-Carey project, at Nelson's ranch, 11 miles northwest of Dupuyer, in Teton County.

DRAINAGE AREA.—Not measured.

RECORDS AVAILABLE.—May 8, 1914, to September 30, 1917.

GAGE.—Vertical iron staff on right bank a short distance above the ranch building; read since July 1, 1916. The inclined wooden staff at same location and datum used prior to June 18, 1916, was destroyed by flood June 19–21, 1916; gage read by John Ryan.

DISCHARGE MEASUREMENTS.—Made by wading 100 feet above gage.

CHANNEL AND CONTROL.—Composed of cobblestones and gravel; shifts at extreme floods. Occasionally obstructed by growth of aquatic plants in summer.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 5.30 feet June 18 (discharge, 1,040 second-feet); minimum stage recorded was 2.70 feet September 22, 25, and 26 (discharge, 14 second-feet).

1914–1917: Maximum stage recorded, 5.30 feet June 18, 1917 (discharge, 1,040 second-feet); a higher stage occurred June 19–21, 1916, when gage was washed away (stage and discharge unknown). No flow October 18–24, 1914, March 28 to April 5 and April 8–30, 1915.

ICE.—Stage-discharge relation seriously affected by ice December 8 to March 19; data are inadequate to compute flow for period; gage-height record practically complete for period.

DIVERSIONS.—The B canal and several small ditches divert water above station.

REGULATION.—Except during floods, the discharge is controlled by Swift dam and by the headworks of B canal.

ACCURACY.—Stage-discharge relation permanent during open-channel periods. Rating curve based on 6 measurements and is very well defined between 25 and 350 second-feet. Gage read to hundredths once daily. Daily discharge ascertained by applying daily gage height to rating table. Records good.

COOPERATION.—Gage heights and some of discharge measurements furnished by engineering department of Valier-Montana Land & Water Co.

Discharge measurements of Birch Creek at Nelson's ranch, near Dupuyer, Mont., during the year ending Sept. 30, 1917.

BIRCH CREEK AT ROBARE, MONT.

LOCATION.—In N. ½ sec. 31, T. 30 N., R. 7 W., near former post office of Robare, 14 miles west of Valier and 10 miles north of Dupuyer, in Teton County.

DRAINAGE AREA.—Not measured.

RECORDS AVAILABLE.—June 4, 1914, to September 30, 1917.

GAGE.—An inclined staff on right bank, half a mile downstream from old post office at Robare. This was washed out in spring of 1917. April 14, 1917, a vertical steel staff graduated to tenths was installed at the same location and the same datum.

DISCHARGE MEASUREMENTS.—Made by wading near the gage.

CHANNEL AND CONTROL.—Bed of stream is composed of cobblestones and is fairly permanent. Stream flows in two channels at high stages.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 3.45 feet June 18 (discharge, 870 second-feet); minimum stage recorded, 1.25 feet September 26 (discharge, 24 second-feet).

1914–1917: Maximum stage recorded, 4.11 feet June 17, 1916 (discharge, 1,010 second-feet); minimum stage, 1.64 feet May 11, 1915 (discharge, 0.4 second-foot).

ICE.—Stage-discharge relation seriously affected by ice. Observations discontinued November 10 to April 13.

DIVERSIONS.—Most of water at ordinary stages is diverted or stored above station.

REGULATION.—Discharge largely controlled by operation of Swift dam, the B canal headworks, and several smaller ditches.

ACCURACY.—Stage-discharge relation affected by shifting control. The rating curves are well defined except at high stages. Shifting-control method used July 11–19. Gage read to hundredths once daily. Daily discharge obtained by applying daily gage height to rating table. Records good.

COOPERATION.—Discharge measurements and gage heights furnished by engineering department of Valier-Montana Land & Water Co.

Discharge measurements of Birch Creek at Robare, Mont., during the year ending Sept. 30, 1917.

DUPUYER CREEK NEAR VALIER, MONT.

LOCATION.—In NE. ¼ NW. ¼ sec. 33, T. 29 N., R. 6 W., at Cowell ranch, 1,000 feet above diversion dam at head of D canal from Dupuyer Creek to Lake Frances reservoir and outlet of B canal, which diverts water from Birch Creek to Dupuyer Creek; 6 miles below mouth of Sheep Creek and 11 miles southwest of Valier, Teton County, the nearest railway point.

DRAINAGE AREA.—111 square miles (measured by Valier-Montana Land & Water Co.).

RECORDS AVAILABLE.—July 17, 1912, to September 30, 1917.

GAGE.—Vertical steel staff on right bank, 1,000 feet above diversion dam, since June 23, 1916; read by E. D. Perkins. An overhanging chain gage was used to May 15, 1913; a vertical wooden staff May 16, 1913, to April 1, 1914; an inclined wooden staff April 2, 1914, to March 12, 1915; and a vertical steel staff March 13, 1915, to February 17, 1916, when it was bent over by ice. The inclined wooden staff was read until a new vertical steel staff was set March 24, which was read until both it and the inclined wooden staff were washed out on June 21; datum unchanged; all gages at same site. A Bristol water-stage recorder was installed but has not been used since 1912, and the well was completely washed out June 21, 1916.

DISCHARGE MEASUREMENTS.—Made by wading at low stages. High-water measurements made by floats, or from bridge 5 miles below gage. Cable 30 feet below gage has not been repaired since support on right bank was undermined June 21, 1916.

CHANNEL AND CONTROL.—Bed of stream coarse gravel; right bank high and steep; left slopes gradually and is overflowed only at flood stage. A bar or ledge that produces a riffle about 400 feet below the gage forms the control at certain stages. Measuring section obstructed during the late summer and fall by growth of algae.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 6.94 feet March 29 at 9.50 a. m. (discharge, 1,500 second-feet, based on measurements made March 28 and 29); minimum open-water stage, 2.76 feet September 23 at 3 p. m. (discharge, 25 second-feet). A lower minimum occurred during winter as indicated by measurement of March 16.

1912–1917: Maximum stage recorded, 6.5 feet on June 21, 1916, determined by level from flood marks (discharge, 2,180 second-feet); minimum stage, 2.22 feet August 9, 1914 (discharge, 4.4 second-feet).

ICE.—Stage-discharge relation seriously affected by ice. Discharge November 15–30 and March 1 to April 9 estimated by comparison with Birch Creek and by special study in connection with temperatures and measurements made during winter. No discharge computed December 1 to February 28.

DIVERSIONS.—A number of small ditches divert water for irrigation from Dupuyer Creek and tributaries; many of the numerous water-right filings have been perfected by use.

Regulation. None.

Accuracy.—Stage-discharge relation changed during the last part of April. Rating curve used for the open-water periods October 1 to April 17 well defined between 50 and 1,800 second-feet; shifting-control method used April 18–30; curve used May 1 to September 30 well defined between 20 and 2,000 second-feet. Gage read to hundredths once daily. Daily discharge ascertained by applying daily gage height to rating table.

Discharge measurements of Dupuyer Creek near Valier, Mont., during the year ending Sept. 30, 1917.

CUT BANK CREEK AT CUT BANK, MONT.

LOCATION.—In SW. ¼ sec. 1, T. 33 N., R. 6 W., at Great Northern Railway bridge 12 miles above junction with Two Medicine River, half a mile west of Cut Bank, in Toole County.

DRAINAGE AREA.—971 square miles.

RECORDS AVAILABLE.—August 4, 1905, to September 30, 1917.

GAGE.—Vertical staff nailed to pier protecting left bank of creek 10 feet above center line of Great Northern Railway bridge; used since August 31, 1911; prior to that date, a chain gage on left bank 200 yards farther downstream. Read by Charles Ferres.

DISCHARGE MEASUREMENTS.—Made from highway bridge a quarter of a mile below gage or by wading.

CHANNEL AND CONTROL.—Rock and gravel bar 200 feet below gage forms principal control; shifts. At high stages creek is 200 to 300 feet wide, but at low stages narrows at principal control.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 6.1 feet at 7 a. m. June 12 (discharge, 1,740 second-feet); minimum stage recorded, 3.80 feet September 19–21 (discharge, 20 second-feet).

1905–1917: Maximum stage recorded, 10.0 feet June 5, 1908, (discharge computed from extension of rating curve, 8,810 second-feet); minimum, 2.5 feet November 29, 30, 1905 (discharge, 5 second-feet).

ICE.—Stage-discharge relation seriously affected by ice; observations discontinued during winter.

DIVERSIONS.—Intake of Great Northern Railway's pumping station is 100 feet below gage; average quantity pumped is about 14,000 gallons an hour for 18 hours a day, equivalent to a continuous flow of 0.4 second-foot. There are also some small diversions for irrigation on the Blackfeet Indian Reservation above gage.

REGULATION.—None.

ACCURACY.—Stage-discharge relation seriously affected by ice and by radical changes in the control. Rating curve used October 1 to November 9 fairly well defined; curve used April 11 to May 12 and May 27 to August 24 well defined between 60 and 1,600 second-feet; shifting-control method used August 25 to September 30. Gage read to half-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records only fair, as observer's readings have been found in error occasionally.

Discharge measurements of Cut Bank Creek at Cut Bank, Mont., during the year ending Sept. 30, 1917.

[Made by W. A. Lamb.]

TETON RIVER AT STRABANE, MONT.

LOCATION.—In SE. ¼ NE. ¼ sec. 35, T. 25 N., R. 7 W., at highway bridge on Peebles's ranch, at Strabane, in Teton County, 16 miles above Chouteau.

DRAINAGE AREA.—Not measured.

RECORDS AVAILABLE.—November 26, 1904, to December 31, 1906, and June 1, 1908, to September 30, 1917.

GAGE.—Chain gage on upstream side of highway bridge installed March 23, 1911; read by Jas. Peebles, jr. November 26, 1904, to March 8, 1905, a staff gage 40 feet above head of Kroff's irrigation ditch; March 9, 1905, to May 7, 1906, a staff gage 250 feet upstream; May 8, 1906, to December 31, 1906, a staff gage at Bjornstad's ranch 1½ miles above gage at site of gage used to May 7, 1906. All gages at different datums.

DISCHARGE MEASUREMENTS.—Made by wading or from bridge.

CHANNEL AND CONTROL.—Bed composed of coarse gravel, likely to shift. Several channels at medium and high stages.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year 6.45 feet at 11 a. m. May 26 (discharge, 2,460 second-feet); minimum stage, 3.15 feet March 13 (discharge, 42 second-feet).

ICE.—Stage-discharge relation seriously affected by ice except for short periods, as current is swift and river is seldom under complete ice cover.

DIVERSIONS.—The Teton Cooperative Co.'s canal diverts water 1 mile above gage for a Carey Act project.

ACCURACY.—Stage-discharge relation changed during May. Rating curve used October 1 to May 12 well defined below 2,000 second-feet; curve used May 28 to September 30 well defined between 70 and 1,000 second-feet; shifting-control method used May 13–27. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records good, except those for May 13–27, which are fair.

Discharge measurements of Teton River at Strabane, Mont., during the year ending Sept. 30, 1917.

TETON RIVER NEAR CHOUTEAU, MONT.

LOCATION.—On south line of SW. ¼ sec. 25, T. 24 N., R. 5 W., at highway bridge 1½ miles southwest of Chouteau, Teton County.

DRAINAGE AREA.—Not measured.

RECORDS AVAILABLE.—November 30, 1904, to July 31, 1906; May 27 to December 6, 1913; and April 14, 1915, to September 30, 1917.

GAGE.—Vertical staff fastened to pile on downstream side of bridge near left bank; read by M. G. Read. Original gage, a chain attached to upstream handrail of bridge, was stolen before any observations were made; replaced May 9, 1905, by chain gage at same datum fastened to floor of bridge. Gage used in 1913 same as that used in 1915–16.

DISCHARGE MEASUREMENTS.—Made by wading from bridge at gage, or from bridge 2 miles below gage. If made from lower bridge, the flow of Deep Creek is deducted

CHANNEL AND CONTROL.—Stream bed gravelly and likely to shift. Right bank high and not subject to overflow; left bank lower and may be overflowed during extreme floods.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 7.1 feet June 18 (discharge 1,550 second-feet); water was over top of gage, 6.7 feet, May 21–29; minimum stage recorded, 3.45 feet September 17 (discharge, 2.8 second-feet).

1904–1906, 1913, and 1915–1917: Maximum stage recorded, 8.7 feet June 21, 1916 (determined from flood marks) (discharge not determined); minimum discharge recorded 1 second-foot August 9–16, 20, 1913. Discharge also estimated at 1 second-foot several days in April, May, and July, 1906.

ICE.—Stage-discharge relation seriously affected by ice; observations discontinued during winter.

DIVERSIONS.—Numerous diversions above gage for irrigation. See miscellaneous measurements, page —.

REGULATION.—Low flow during summer caused by diversions.

ACCURACY.—Stage-discharge relation not permanent; affected by shifting control, by ice, and by drift lodged against pier of bridge. Rating curve used October 1 to December 19 fairly well defined below 1,000 second-feet; curve used April 14 to May 13, and June 18 to September 30 well defined below 1,000 second-feet. May 14–22, and May 30 to June 17 stage-discharge relation seriously affected by brush lodged against bridge pier; discharge obtained by indirect method for shifting control. May 23–29 water above gage; flow not computed on account of uncertainty in flow in canals above station. Records poor owing to unsatisfactory gage-height record during most of year.

Discharge measurements of Teton River near Chouteau, Mont., during the year ending Sept. 30, 1917.

NOTE.—Gage read on following days: Oct. 2, 4, 6, 11-12, 14-15, 18-23, 25-29, 31; Nov. 2, 4, 6, 8, 11-12, 16, 28; Dec. 1-3, 5, 8, 10, 12, 14, 17, 19. No gage readings Dec. 20 to Apr. 13; Apr. 14-30; May 1-20, 22, 30-31; June 1-12, 14-30; July 1-8; 20, 23; Aug. 16-18, 24; Sept. 17. Discharge interpolated for days of missing gage readings Oct. 1 to Dec. 19, May 21, and June 13. Stage above top of gage, May 23-29; discharge not computed on account of numerous diversions between this station and the one at Strabane.

Monthly discharge of Teton River near Chouteau, Mont., for the year ending Sept. 30, 1917.

Month.	Discharge in second-feet.			Run-off in acre-feet.
	Maximum.	Minimum.	Mean.	
October	86	56	67.5	4,150

SPRING CREEK NEAR STRABANE, MONT.

Location.—In NE. ¼ SE. ¼ sec. 2, T. 24 N., R. 7 W., at highway bridge half a mile southeast of buildings on Peebles ranch, and 16 miles west of Chouteau, Teton County.

Drainage area.—Not measured.

Records available.—May 30 to December 31, 1913, and April 14 to September 30, 1917.

Gage.—Vertical staff on left bank at upstream side of wagon bridge. From May 30 to December 31, 1913, the gage used was a staff on the left bank, 200 feet above the highway bridge.

Discharge measurements.—Made from bridge or by wading.

Channel and control.—Banks low; covered with grass above gage and with brush below bridge; not subject to overflow except during extreme high water. Bed composed of earth, sand, and gravel, and is fairly permanent.

Extremes of discharge.—Maximum stage recorded during year, 2.44 feet at 4 p. m. May 31 (discharge, 66 second-feet); minimum stage, 0.06 foot July 30 to August 3 (discharge, 0.9 second-foot).

1913 and 1917: Maximum stage recorded 2.44 feet at 4 p. m. May 31, 1917 (discharge, 66 second-feet); minimum discharge, 0.5 second-foot August 26, 1913.

Ice.—Stage-discharge relation not seriously affected by ice; open-channel rating applicable.

Diversions.—None.

Regulation.—None.

Accuracy.—Stage-discharge relation permanent during the year; not affected by ice. Rating curve well defined between 1 and 22 second-feet. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records good.

Discharge measurements of Spring Creek near Strabane, Mont., during the year ending Sept. 30, 1917

SPRING CREEK NEAR CHOUTEAU, MONT.

Location.—At McDonald's ranch, near east line of sec. 33, T. 25 N., R. 6 W., half a mile above mouth and 13 miles northwest of Chouteau, in Teton County.

Records available.—April 13 to September 30, 1917.

Drainage area.—Not measured.

Gage.—Vertical staff with enamel face, on right bank 100 feet below wagon bridge; read by Roland Brooks and Katherine McDonald.

Discharge measurements.—Made by wading or from the bridge 100 feet above the gage.

Extremes of discharge.—Maximum stage recorded during year, 3.35 feet at 9 a. m., May 26 (discharge, 138 second-feet); minimum stage, 2.10 feet September 12-30 (discharge, 12.0 second-feet).

Ice.—Station not maintained during winter.

Diversions.—Several small ditches divert some water for irrigation above station; amount is small.

Regulation.—None.

Accuracy.—Stage-discharge relation not permanent. Rating curve used, April 13 to August 23 well defined between 10 and 40 second-feet. Shifting-control method used August 24 to September 30. Gage read to quarter-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records good, April 13 to August 23; fair, August 24 to September 30.

Discharge measurements of Spring Creek near Chouteau, Mont., during the year ending Sept. 30, 1917.

DEEP CREEK NEAR CHOUTEAU, MONT.

LOCATION.—In SW. ¼ NW. ¼ sec. 15, T. 23 N., R. 5 W., at Hugh Robinson's ranch, 5 miles southwest of Chouteau, in Teton County.

DRAINAGE AREA.—Not measured.

RECORDS AVAILABLE.—March 24, 1911, to September 30, 1917.

GAGE.—Overhanging chain on right bank, 400 feet above Hugh Robinson's house; read by Hugh Robinson.

DISCHARGE MEASUREMENTS.—Made by wading.

CHANNEL AND CONTROL.—Bar of gravel 50 feet below gage forms principal control. Channel clean and fairly permanent. Right bank high and not subject to overflow; left bank may be overflowed.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 9.1 feet at 8 a. m. May 26 (discharge, 1,930 second-feet); minimum stage recorded, 5.3 feet March 8, 9, 11–15, 17, 19, 22–26 (discharge, 12 second-feet).

1911–1917: Maximum stage recorded, 10.5 feet, 7 a. m. June 21, 1916 (discharge, from extension of rating curve, 3,050 second-feet); minimum stage recorded, 5.28 feet, September 25, 1913, and 5.27 feet, September 6, 1914 (discharge, 11 second-feet).

ICE.—Stage-discharge relation seriously affected by ice after December 5; observations discontinued December 24 to March 7; flow interpolated November 10–13 on account of ice.

DIVERSIONS.—A few small ditches divert from creek above gage.

REGULATION.—None.

ACCURACY.—Stage-discharge relation changed during high water in May and June; affected by ice. Daily gage heights are from observer's readings to nearest half-tenth once daily. Daily discharge ascertained by applying to daily gage heights for October 1 to November 9, November 14 to December 5, and March 8 to June 24 a rating table well defined below 700 second-feet and fairly well defined above. Daily discharge for the period June 25 to September 30 obtained as above by means of a rating table based upon a curve fairly well defined.

Discharge measurements of Deep Creek near Chouteau, Mont., during the year ending Sept. 30, 1917.

WILLOW CREEK NEAR CHOUTEAU, MONT.

LOCATION.—In sec. 14, T. 23 N., R. 6 W., at McPhee's ranch, 12 miles southwest of Chouteau, in Teton County.

DRAINAGE AREA.—Not measured.

RECORDS AVAILABLE.—April 2, 1912, to September 30, 1917.

GAGE.—Staff gage on left bank, half a mile below house of S. A. McPhee; read by S. A. McPhee.

DISCHARGE MEASUREMENTS.—Made by wading at gage, except at extremely high stages, when they may be made from bridge half a mile below gage.

CHANNEL AND CONTROL.—A gravel bar 30 feet below gage is the control; shifts occasionally. Banks are about 4 feet high and are overflowed only at extreme flood stages.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 5.60 feet at 1.20 p. m. May 26 (discharge, 663 second-feet); minimum stage, 1.13 feet August 25 and 30 (discharge, 0.4 second-foot).

1912-1917: Maximum stage recorded, 6.60 feet June 21, 1916 (discharge, 880 second-feet); minimum stage, dry July 20 to end of season, 1914.

ICE.—Stage-discharge relation seriously affected by ice; observations discontinued during winter; probably little flow.

DIVERSIONS.—Several small diversions above station, mostly to water hay land; very little water used except during very dry periods.

REGULATION.—None.

ACCURACY.—Stage-discharge relation fairly permanent during year; apparently not seriously affected by aquatic growths this year. Rating curve well defined between 3 and 400 second-feet. Gage read to quarter-tenths once daily. Daily discharge ascertained by applying daily gage height to rating table. Records good.

Discharge measurements of Willow Creek near Chouteau, Mont., during the year ending Sept. 30, 1917.

MUDDY CREEK NEAR BYNUM, MONT.

LOCATION.—In NW. ¼ SE. ¼ sec. 22, T. 26 N., R. 6 W., 400 feet above mouth of Blackleaf Creek and 2 miles above Bynum, in Teton County.

DRAINAGE AREA.—Not measured.

RECORDS AVAILABLE.—May 24, 1912, to September 30, 1917.

GAGE.—Vertical staff on right bank; read by George Miller. June 23, 1916, a temporary vertical staff was set about 20 feet downstream to replace regular gage, which had been washed out. July 21, 1916, new low-water staff was set at regular section. Prior to October 5, 1914, gage in use was overhanging chain on left bank 100 feet upstream from present gage, and at different datum.

CHANNEL AND CONTROL.—Stream bed sand and gravel; may shift. Left bank high and not subject to overflow; right bank gradually sloping; apparently one channel at all stages.

Extremes of discharge.—Maximum stage recorded during year, 5.90 feet at 7.50 a. m. May 26 (discharge, 720 second-feet); minimum stage, 2.30 feet September 1–24 (discharge, 1.0 second-feet).

1912–1917: Maximum stage recorded, 6.9 feet June 21, 1916, determined by leveling from flood marks (discharge, determined from extension of rating curve, 976 second-feet); channel dry August 18, 23, 24, 31; September 1–3, 10, 29; and October 7, 1912.

Ice.—Ice present November 9–11; discharge not computed; no readings, November 12, to April 1.

Diversions.—Three small ditches divert above the station, and the Teton Cooperative Co. proposes to store the flood waters.

Regulation.—None.

Accuracy.—Stage-discharge relation not permanent, owing to shifting control and ice. Rating curve used October 1 to November 8 well defined below 600 second-feet; curve used April 2 to May 20 poorly defined; June 7 to September 30, fairly well defined; shifting-control method used May 21–29. Gage read to quarter-tenths twice daily April 20 to June 10, and once daily during rest of year. Daily discharge ascertained by applying daily gage height to rating table. Records good.

Discharge measurements of Muddy Creek near Bynum, Mont., during the year ending Sept. 30, 1917.

NOTE.—See footnote to daily discharge table regarding discharge May 30 to June 6, 1917.

MUDDY CREEK NEAR AGAWAM, MONT.

LOCATION.—In sec. 35, T. 26 N., R. 4 W., at highway bridge 2 miles southeast of Agawam, in Teton County.

DRAINAGE AREA.—Not measured.

RECORDS AVAILABLE.—June 17 to September 30, 1917, when station was discontinued.

GAGE.—Wire gage on the downstream handrail of bridge near left bank, read by Wm. Moser.

DISCHARGE MEASUREMENTS.—Made by wading or from highway bridge.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 3.18 feet June 17 (discharge, 150 second-feet); minimum stage, 1.50 feet September 20 (discharge, 9 second-feet).

ICE.—Station not maintained during winter.

DIVERSIONS.—Several ditches divert water for irrigation above station.

REGULATION.—Flow increased by Teton Cooperative Reservoir.

ACCURACY.—Stage-discharge relation changed July 1-17. Rating curve used June 17 to July 1 well defined below 152 second-feet; curve used July 18 to September 30 well defined between 8 and 109 second-feet; shifting-control method used July 2-17. Gage read to hundredths once daily. Daily discharge ascertained by applying daily gage height to rating table. Records good, except those for July 2-17, which are fair.

Discharge measurements of Muddy Creek near Agawam, Mont., during the period June 17 to Nov. 8, 1917.

BLACKLEAF CREEK NEAR BYNUM, MONT.

LOCATION.—In NW. ¼ SE. ¼ sec. 22, T. 26 N., R. 6 W., 200 feet above mouth of creek and 2 miles above Bynum, in Teton County.

DRAINAGE AREA.—Not measured.

RECORDS AVAILABLE.—May 24, 1912, to September 30, 1917.

GAGE.—Overhanging chain gage on left bank, 100 feet west of an abandoned barn: read by George Miller.

DISCHARGE MEASUREMENTS.—Made by wading near gage.

CHANNAL AND CONTROL.—Banks fairly high, and not subject to overflow. Stream bed fine sand and gravel; shifts occasionally.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 5.0 feet May 26 (discharge, 333 second-feet); minimum stage recorded, 2.78 feet July 31, August 1–4 and 26 (discharge, 0.1 second-feet).

1912–1917: Maximum stage recorded, 5.85 feet June 21, 1916, determined by leveling from flood marks (discharge, determined from extension of rating curve, 600 second-feet); channel dry July 21 to October 3, 1914.

ICE.—Stage-discharge relation seriously affected by ice; observations discontinued during winter.

DIVERSIONS.—Most of flow at low stages is diverted above station for irrigation, and Teton Cooperative Reservoir Co. proposes to use the flood waters.

REGULATION.—None.

ACCURACY.—Stage-discharge relation changed during April and May. Rating curve used October 1 to November 7 well defined below 400 second-feet; shifting-control method used April 3 to June 2; curve used June 3 to September 30 well defined below 100 second-feet. Gage read to quarter-tenths once daily; occasionally twice daily. Daily discharge ascertained by applying daily gage height to rating table. Records good, October 1 to November 7 and after June 2; fair, April 3 to June 3.

Discharge measurements of Blackleaf Creek near Bynum, Mont., during the year ending Sept. 30, 1917.

MUSSELSHELL RIVER BASIN.

MUSSELSHELL RIVER AT HARLOWTON, MONT.

LOCATION.—In sec. 26, T. 8 N., R. 15 E., at highway bridge 1 mile south of Harlowton, Meagher County.

DRAINAGE AREA.—Not measured.

RECORDS AVAILABLE.—July 11, 1907, to September 30, 1917.

GAGE.—Chain gage on upstream side of public highway bridge; read by W. G. Yamamoto. Before October, 1908, a staff gage fastened to the center pier of old highway bridge was read. April 10, 1909, a temporary staff gage was installed which read 0.73 foot high. This gage was used until May 24, 1909, when gage was lowered and the datum changed, so that the difference between the bench mark and the zero of the gage is 0.52 foot greater than formerly. No change has been made in gage or datum since May 24, 1909.

DISCHARGE MEASUREMENTS.—Made from bridge or by wading.

CHANNEL AND CONTROL.—Stream bed composed of sand and gravel; bar or ridge crosses the stream about 75 feet below the gage; shifts. Banks fairly high and probably not subject to overflow. Water confined to one channel under bridge, owing to road fill at the ends.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 5.3 feet at 8 a. m. May 27 (discharge, 4,020 second-feet); minimum stage, 0.52 foot August 30 (discharge, 43 second-feet).

1907-1917: Maximum stage recorded, 5.3 feet at 8 a. m. May 27, 1917 (discharge, 4,020 second-feet); minimum stage recorded, dry August 4-11, 1910.

ICE.—Stage-discharge relation seriously affected by ice; observations discontinued during winter.

DIVERSIONS.—Numerous ditches divert from headwater streams, and from Musselshell River above station.

REGULATION.—None.

ACCURACY.—Stage-discharge relation changed during April. Rating curve used October 1 to December 23 and April 26 to September 30 well defined above 40 second-feet. Shifting-control method used April 1-25. Gage read to quarter-tenths twice daily. Daily discharge ascertained by applying mean daily gage heights to rating table. Records fair.

Discharge measurements of Musselshell River at Harlowton, Mont., during the year ending Sept. 30, 1917.

[Made by C. S. Heidel.]

FLATWILLOW CREEK NEAR FLATWILLOW, MONT.

LOCATION.—In sec. 23, T. 12 N., R. 25 E., at Flatwillow Ranch Co.'s ranch, 8 miles above Flatwillow, Fergus County, and 30 miles north of Roundup.

DRAINAGE AREA.—200 square miles (measured on 1916 map of Fergus County).

RECORDS AVAILABLE.—May 1, 1911, to September 30, 1917.

GAGE.—Vertical staff just below wagon bridge near the ranch buildings; read by J. D. Brinegar.

DISCHARGE MEASUREMENTS.—Made from footbridge at house, or by wading at ford below house.

CHANNEL AND CONTROL.—Banks high and thickly overgrown with willows. Stream bed earth; current sluggish; weeds grow in bed during summer; control shifts.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year 9.0 feet, estimated by observer June 4–11 (discharge, 454 second-feet in creek and 500 second-feet additional in canal); minimum stage recorded, 2.45 feet October 13–16 (discharge, 26 second-feet).

1911–1917: Maximum stage recorded 9.0 feet, estimated by observer June 4–11, 1917 (discharge, 454 second-feet in creek and 500 second-feet additional in canal); minimum stage 2.1 feet September 3, 4, 1912 (discharge, 1.0 second-foot).

ICE.—Stage-discharge relation seriously affected by ice; data inadequate to warrant estimates of winter flow.

DIVERSIONS.—Numerous above gage. The diversion canal of the Flatwillow Carey project heads about 3 miles upstream from the station. The wooden head gate washed out, allowing considerable water to pass through the canal without ever passing gage. This is listed under "Overflow in Flatwillow canal."

REGULATION.—None.

ACCURACY.—Stage-discharge relation changed by ice conditions which prevailed November 11 to April 10. Rating curve used to June 4 well defined below 100 second-feet and fairly well defined above that stage. Rating curve used June 21 to September 30 fairly well defined. Canal discharge can be considered at best as only fair, because of the indirect methods used in deriving them. Creek gage read to half-tenths daily. Daily discharge of creek ascertained by applying daily gage height to rating table. Total daily discharge May 12 to September 30 obtained by adding daily discharge of creek to discharge of canal. Records good, except May 12 to about September 30, for which period they are fair.

Discharge measurements of Flatwillow Creek near Flatwillow, Mont., during the year ending Sept. 30, 1917.

[Made by C. S. Heidel.]

Date.	Gage height.	Discharge.
	Feet.	*Sec.-ft.*
Apr. 6	3.8	[a]50

September	55	47	49.1	2,920

NOTE.—Figures for May 12 to September 30 include estimates of flow in canal.

MILK RIVER BASIN.

SOUTH FORK OF MILK RIVER NEAR INTERNATIONAL BOUNDARY.

LOCATION.—In SW. ¼ sec. 29, T. 37 N., R. 9 W., at Richard Croff's ranch, just above Kennedy Coulee, in Teton County, 5 miles south of international boundary and 30 miles northeast of Browning.

DRAINAGE AREA.—288 square miles (measured on topographic maps).

RECORDS AVAILABLE.—April 28, 1905, to September 30, 1917.

GAGE.—Stevens water-stage recorder installed April 13, 1913, on left bank, opposite house of observer; April 28 to May 8, 1905, a staff; May 8, 1905, to Apr. 13, 1913, an overhanging chain gage. Gage read by Wm. Welch to May 31, 1917; thereby Mrs. Viola Saffell.

DISCHARGE MEASUREMENTS.—Made from cable 100 feet below gage or by wading.

CHANNEL AND CONTROL.—Bottom of channel is composed of clay and small boulders. Growth of aquatic plants affects stage-discharge relation at low stages during summer. Banks are high and not subject to overflow.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 6.42 feet at 6 p. m., August 8 (discharge, 1,520 second-feet); minimum stage recorded 2.5 feet November 8 (discharge, 18 second-feet).

1905–1917: Maximum stage recorded 15.4 feet June 6, 1908, determined from high-water marks (discharge not computed); flood width 850 feet; flood cross section about 2,600 square feet. Minimum stage recorded, 2.9 feet August 18–20, 1906 (discharge, 1 second-foot).

ICE.—Stage-discharge relation affected by ice for short periods.

DIVERSIONS.—None.

REGULATION.—None.

ACCURACY.—Stage-discharge relation affected by ice and shifting control. Rating curves were used directly or indirectly as follows: curve well defined between 40 and 1,520 second-feet October 1 to December 31; well defined between 21 and 1,430 second-feet January 5–10 and April 4 to September 30; and well defined between 20 and 40 second-feet January 19 to April 3. Gage heights from automatic record April 4–15, 28, May 1, 2, 5, 29, 30 and June 11–13; observer's readings used for rest of the year. Observer read to half-tenths daily to May 31, and to hundredths daily thereafter. Discharge determined by applying gage height to rating table directly October 1 to December 17, January 5–10, January 19 to April 3, April 4–10, May 17–31, June 21 to July 11, and August 9 to September 30; shifting-control method used January 11–18, April 11 to May 16, June 1–20, and July 12 to August 8. Records good.

COOPERATION.—Station maintained in cooperation with the Reclamation Service, Department of the Interior, Canada.

Discharge measurements of South Fork of Milk River near international boundary during the year ending Sept. 30, 1917.

MILK RIVER AT EASTERN CROSSING,[1] MONT.

LOCATION.—In NE. ¼ sec. 5, T. 37 N., R. 9 E.,[2] at international boundary, 30 miles north of Rudyard, Hill County, Mont., and 37 miles south of Many Berries, Alberta, the nearest railway stations.

DRAINAGE AREA.—2,514 square miles (measured by engineers of the Reclamation Service, Department of the Interior, Canada).

[1] Formerly called Milk River at international boundary.

[2] Station located on south side instead of north side of international boundary as given in Water Supply Paper 436.

RECORDS AVAILABLE.—April 1, 1913, to September 30, 1917. From August 7, 1909, to April 1, 1913, station was maintained by Irrigation Branch (now Reclamation Service), Department of the Interior, Canada.

GAGE.—Gurley printing gage on right (south) bank installed September 18, 1917, and used to September 30, 1917; referred to two staff gages, one inside of well and the other in trench outside. April 1, 1913, to August 13, 1913, staff gage on left (north) bank 200 feet below present gage. August 13, 1913, to March 22, 1917, Gurley printing gage referred to staff gage in river 10 feet below gage house. April 9 to June 13, 1917, several temporary gages were used, but all readings have been referred to the staff gage at the site of the one used August 13, 1913, to March 22, 1917. June 14 to September 18, readings on a staff gage at present location. The zero of the north bank gage to which readings to June 14 are referred is at elevation 2,696. 58 feet above sea level, and the present south bank gage to which readings after June 14 are referred is 2,698.92 feet above sea level.

DISCHARGE MEASUREMENTS.—Made from cable 90 feet below gage or by wading.

CHANNEL AND CONTROL.—A bar composed of heavy boulders, gravel, and sand makes a decided riffle at medium and low stages: shifts occasionally.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 9.60 feet, April 9 (discharge, 4,860 second-feet); minimum stage, lowest recorded discharge was that of discharge measurement of March 10, of 23 second-feet; stage-discharge relation seriously affected by ice, and lower stages may have occurred during winter.

1909–1917: Maximum stage recorded, that of April 9, 1917; minimum stage, channel recorded dry August 3–17, 22, 23, 1914.

ICE.—Stage-discharge relation seriously affected by ice November 6 to April 8.

DIVERSIONS.—None.

REGULATION.—Low-water flow materially increased by water from St. Mary canal during July, August, and September.

ACCURACY.—Stage-discharge relation affected by ice and shifting control. Rating curves as follows were used during the year: fairly well defined October 1 to November 5; fairly well defined May 1 to June 6; and well defined between 100 and 1, 600 second-feet June 15 to September 30. Gage heights from observer's readings until September 17 and from automatic gage September 17–30. Discharge ascertained by applying gage height to rating tables; shifting-control methods used April 9–30 and June 7–14. Records October 1 to November 6, May 1 to June 6, and after June 15 good; records November 7 to April 8 poor; and records April 9–30 and June 7–14 fair.

COOPERATION.—Maintained in cooperation with Reclamation Service, Department of the Interior, Canada.

Discharge measurements of Milk River at eastern crossing, Mont., during the year ending Sept. 30, 1917.

[a] Flow estimated from flow of Milk River at Milk River and at Havre. See footnote to table of daily discharge.
[b] Apr. 1-8 estimated. See footnote to table of daily discharge.

MILK RIVER AT HAVRE, MONT.

LOCATION.—In SW. ¼ SW. ¼ sec. 4, T. 32 N., R. 16 E., at highway bridge over Milk River at Havre, in Hill County.

DRAINAGE AREA.—Not measured.

RECORDS AVAILABLE.—May 15, 1898, to September 30, 1917.

GAGE.—Chain gage fastened to downstream rail of bridge; read by Chas. Ling, jr. Owing to shifting of bed of river, it has often been necessary to move gage from one end of bridge to the other, but the datum has not been changed.

DISCHARGE MEASUREMENTS.—Made from highway bridge or by wading.

CHANNEL AND CONTROL.—Bed of stream composed of fine gravel and sand, shifting frequently. Both banks are overflowed at high stages.

EXTREMES OF DISCHARGE.—Maximum stage recorded during the year, 15.3 feet April 10 (stage-discharge relation affected by ice); maximum discharge occurred April 11 at stage 15.15 feet (discharge, 7,940 second-feet); minimum stage recorded, 5.83 feet February 13 and March 17; flow not computed on account of ice.

1898–1917: Maximum stage recorded, 17.2 feet March 12, 1916 (discharge not known); minimum stage recorded, channel recorded dry July 16–18, 1898, August 16–20, 1904, July 25, August 18–26, 1905, November 16 to December 31, 1906, July 28 to September 14, 1910, and July 29 to August 22, 1914.

ICE.—Stage-discharge relation affected by ice November 11 to April 8.

DIVERSIONS.—None.

REGULATION.—During 1917, the St. Mary canal was in operation and a total of 33,600 acre-feet was added to Milk River flow.

ACCURACY.—Stage-discharge relation affected by ice and shifting control. Rating curve well defined between 100 and 1,500 second-feet used October 1 to November 10 and April 11 to May 15; well defined between 100 and 750 second-feet used June 16 to August 18; and well defined between 100 and 400 second-feet used August 28 to September 30. Gage heights from observer's readings twice daily during open channel and three times a week during ice season. Discharge determined by applying gage heights to rating tables. Shifting-control method used May 16 to June 15 and August 18 to 27. Records good for periods covered by rating tables and fair for other periods.

Discharge measurements of Milk River at Havre, Mont., during the year ending Sept. 30, 1917.

NOTE.—Flow not computed for period Nov. 11 to Mar. 27; gage heights reported approximately 3 times a week. Discharge Mar. 28 to Apr. 10 determined from discharge measurements of Mar. 31 and Apr. 9 and daily gage heights for period. No gage reading on following days: Apr. 19, May 6, 20, 29, June 10, 17, July 1-12, Aug. 28, Sept. 17 and 29. Flow interpolated for all, except July 1-12, which has been computed at 370 second-feet daily after comparison with Milk River at eastern crossing.

Monthly discharge of Milk River at Havre, Mont., for the year ending Sept. 30, 1917.

Month.	Discharge in second-feet.			Run-off in acre-feet.

MILK RIVER AT MALTA, MONT.

LOCATION.—In NW. ¼ sec. 17, T. 30 N., R. 30 E., at old highway bridge at Malta, in Phillips County.

DRAINAGE AREA.—Not measured.

RECORDS AVAILABLE.—July 31, 1902, to September 30, 1917.

GAGE.—Chain fastened to handrail on downstream side of bridge; read by employees of United States Reclamation Service.

DISCHARGE MEASUREMENTS.—Made from bridge or by wading.

CHANNEL AND CONTROL.—Bed of stream composed of gravel; permanent except for slight shifts at low stages. Partial control at gage at low water, but the principal control is formed by a bar or ridge that produces a riffle considerably below the gage.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 19.05 feet at 9 a. m. April 6 (discharge, 10,000 second-feet); minimum stage recorded, 1.05 feet at 4 p. m. August 6 (discharge, 48 second-feet). Lower flow may have occurred during winter.

1902–1917: Maximum stage recorded, 19.75 feet, April 10, 1907 (discharge, 11,200 second-feet); channel recorded dry August 13 to November 10, 1904; April 24 to May 8, and August 30 to end of year, 1905; April 10, 27–29, May 1, 4–23, 1906; July 16 to December 8, 1910.

ICE.—Stage-discharge relation affected by ice December 6–20 and March 30 to April 5.

DIVERSIONS.—Entire run-off from drainage basin above does not pass the station for seven irrigation canals, used to irrigate about 25,000 acres of land, divert water from Milk River and its tributaries between Havre and Malta. The United States Reclamation Service has constructed a diversion dam at Dodson, 17 miles above station, which will eventually divert water to irrigate about 108,000 acres in Milk River Valley. East of Malta two canals are nearing completion, one on each side, their combined capacity will be 1,000 second-feet.

REGULATION.—Part of flood flow will be diverted into Nelson reservoir and held for use in irrigation.

ACCURACY.—Stage-discharge relation practically permanent except when affected by ice. Rating curve very well defined was used October 1 to December 5 and April 6 to September 30. Gage read to half-tenths twice daily October 1 to December 16 and March 30 to May 17, and to half-tenths once daily May 18 to September 30. Discharge determined by applying gage height to rating table. Records good.

Discharge measurements of Milk River at Malta, Mont., during the year ending Sept. 30, 1917.

September	220	64	84.7	5,040

NOTE.—Stage-discharge relation affected by ice Dec. 6-20 and Apr. 1-5.

MILK RIVER NEAR VANDALIA, MONT.

LOCATION.—In sec. 7, T. 30 N., R. 37 E., at Vandalia dam of United States Reclamation Service, 2 miles west of Vandalia, in Valley County.

DRAINAGE AREA.—Not measured.

RECORDS AVAILABLE.—May 5, 1915, to September 30, 1917. Station maintained at Hinsdale, 8 miles upstream from May 13, 1908, to November 13, 1914. Discharge nearly same at both points.

GAGE.—Sloping gage painted on concrete of right abutment downstream side of dam; read by employees of United States Reclamation Service.

DISCHARGE MEASUREMENTS.—Made from bridge over crest of dam or by wading. High-water measurements prior to 1917 made from highway bridge at Vandalia, 4 miles downstream.

CHANNEL AND CONTROL.—Channel of sand and gravel. Control for medium and low stages is a gravel bar; no definite control for high stages.

EXTREMES OF DISCHARGE.—Maximum stage reported during year, 34.5 feet at 5 p. m., April 11 (discharge, 25,200 second-feet); minimum stage, 3.9 feet September 2-14 (discharge, 32 second-feet).

1908–1917: Maximum stage, that of April 11, 1917; channel recorded dry August 9–13, 1910.

ICE.—Stage-discharge relation seriously affected by ice January 1 to March 31, 1917.

DIVERSIONS.—Numerous canals divert water for irrigation from main stream and nearly all tributaries.

REGULATION.—Flow partly regulated by the diversion dams and by storage in Nelson reservoir.

ACCURACY.—Stage-discharge relation affected by ice and shifting control. Rating curves are fairly well defined for periods October 1 to June 27 and June 28 to September 30. Gage heights are subject to error when flow over crest of dam or through gates causes wave action on gage. Gage read to tenths twice daily. Daily discharge ascertained by applying gage height to rating table. Records fair.

Discharge measurements of Milk River near Vandalia, Mont., during the year ending Sept. 30, 1917.

NORTH FORK OF MILK RIVER NEAR INTERNATIONAL BOUNDARY.[1]

Location.—In NE. ¼ sec. 11, T. 1, R. 23 W. fourth meridian, about 300 yards above road crossing at Peters ranch, 2 miles north of international boundary and 18 miles east of Kimball, Alberta.

Drainage area.—101 square miles (measured on topographic maps).

Records available.—January 1, 1913, to September 30, 1917. July 21, 1909, to December 31, 1912, station was maintained by Irrigation Branch (now Reclamation Service), Department of Interior of Canada, in NE. ¼ sec. 13, T. 1, R. 23 W. fourth meridian, 2 miles downstream; May 8, 1911, to December 31, 1912, station was maintained at Alexander Dubray's ranch, 2 miles south of international boundary..

Gage.—Stevens water-stage recorder on left bank; W. Wheeler and Charles Barnett, observers.

Discharge measurements.—Made by wading or from footbridge 700 feet below gage.

Channel and control.—Bed of stream at gage and principal control composed of clay and small boulders; slightly shifting. Banks high and not subject to overflow at ordinary stages.

Extremes of discharge.—Maximum stage recorded during year, 3.95 feet April 9 (discharge, 482 second-feet); minimum discharge, 13.8 second-feet December 29, 1916.

1909–1917: Maximum stage recorded 3.9 feet (referred to station maintained by Canada; see paragraph on "Records available") July 27, 28, 1909 (discharge, 591 second-feet); minimum discharge, 5.0 second-feet February 12, 1916.

Ice.—Stage-discharge relation seriously affected by ice November 11 to April 8.

Diversions.—None.

Regulation.—Amount of water turned into river by St. Mary canal: July, 12,500 acre-feet; August, 15,600 acre-feet; September 1–13, 5,540 acre-feet; approximate total of 33,600 acre-feet.

Accuracy.—Stage-discharge relation affected by ice and shifting control. Rating curves were used as follows: Well defined between 40 and 65 second-feet October 1 to November 10; well defined between 86 and 500 second-feet April 9 to July 1, and August 14 to September 10; well defined between 29 and 46 second-feet September 16–30. Gage heights obtained from water-stage recorder by graphic method October 1 to November 10, April 9 to May 30, and June 21 to September 30. Gage read to half-tenths once daily November 11 to April 5, and May 31 to June 20. Discharge determined by applying gage height to rating table October 1 to November 10, April 9 to July 1, August 14 to September 10, and September

[1] Formerly called "North Fork of Milk River near Kimball, Alberta."

16–30; temperature records, observer's notes, and discharge measurements used November 11 to April 8; and shifting-control method used July 2 to August 13, and September 11–15. Records very good for periods when rating tables were used; fair for other periods.

COOPERATION.—Station maintained in cooperation with Reclamation Service, Department of the Interior, Canada.

Discharge measurements of North Fork of Milk River near international boundary during the year ending Sept. 30, 1917.

The year	482	13.8	120	87,000

NOTE.—Stage-discharge relation affected by ice Nov. 11 to Apr. 8; discharge estimated from discharge measurements, temperature records, and observer's notes.

FORT BELKNAP CANAL NEAR CHINOOK, MONT.

LOCATION.—In SE. ¼ sec. 20, T. 33 N., R. 18 E., at highway bridge half a mile below head gates of canal on Milk River, 8 miles west of Chinook, in Blaine County.

RECORDS AVAILABLE.—June 21, 1903, to September 30, 1917.

GAGE.—Vertical staff on downstream side of first bent of piles from left bank; read by O. E. Walters. Enamel face placed May 3, 1917, with datum raised 0.62 foot at same location. Prior to 1910 gage located at highway bridge a quarter of a mile below. Gage and bridge washed out by high water of June, 1908, and new gage reinstalled June 27, 1908, at different datum within a few feet of old site.

CHANNEL AND CONTROL.—Slope is main factor in determining the flow for given gate opening, but the check weir half a mile below caused backwater at gage. Aquatic plants that grow in canal reduce velocity considerably in latter part of irrigation season.

ACCURACY.—Stage-discharge relation shifting during year. Two rating tables, well defined between 20 and 60 second-feet, were used during the year; one applicable May 6 to May 29 and July 15 to September 30, and the other May 30 to July 14. Gage read to hundredths once daily. Daily discharge determined by applying daily gage heights to rating tables. Records fair.

The water in the Fort Belknap canal is diverted from the north bank of Milk River in SE. ¼ sec. 20, T. 33 N., R. 18 E., to irrigate lands on the north side of the river. Most of water diverted is used, but it can be wasted into Lodge Creek, north of Chinook, 8 miles below the head gate. Check gates erected on the main canal to divert water into the laterals often back the water for long distances. As the gates are put up under a great variety of conditions, velocities differ widely at the same gage height during the season.

Discharge measurements of Fort Belknap canal near Chinook, Mont., during the year ending Sept. 30, 1917.

LODGE CREEK AT INTERNATIONAL BOUNDARY.

LOCATION.—In SE. ¼ sec. 12, T. 1, R. 29 W. third meridian, at Willow Creek barracks of Royal Northwest Mounted Police, 1 mile north of international boundary, in Saskatchewan, Canada, and 36 miles north of Havre, Mont.

DRAINAGE AREA.—806 square miles (measured by engineers of Reclamation Service, Department of Interior, Canada).

RECORDS AVAILABLE.—April 1 to September 30, 1917. April 25, 1910, to October 31, 1916, maintained by Irrigation Branch (now Reclamation Service), Department of Interior, Canada.

GAGE.—Inclined staff on right bank at the Willow Creek post; read by Corl. A. R. Price and William Tudgay.

DISCHARGE MEASUREMENTS.—Made from cable or by wading. Some low-water measurements made with weir.

CHANNEL AND CONTROL.—Composed of heavy boulders, gravel, and sand; shifting.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 10.13 feet April 10 (discharge, 2,100 second-feet); creek dry after July 16.

ICE.—Station discontinued during winter. Stage-discharge relation affected by ice and snow April 1–17.

DIVERSIONS.—Several small ditches divert water for irrigation above station.

REGULATION.—None.

ACCURACY.—Stage-discharge relation affected by ice and shifting control. Rating curve well defined throughout and applicable April 17, 29, May 3, 8–15, 23, 30 to July 16. Gage heights are mean of readings to hundredths twice daily. Discharge determined by applying gage heights to rating table. Shifting-control method used April 7–16, 18–28, 30 to May 2, May 4–7, 16–22, and 24–29. Records fair.

COOPERATION.—Maintained in cooperation with Reclamation Service, Department of Interior, Canada.

Discharge measurements of Lodge Creek at international boundary during the year ending Sept. 30, 1917.

BATTLE CREEK AT INTERNATIONAL BOUNDARY.

LOCATION.—In SE. ¼ sec. 4, T. 1, R. 26 W. fourth meridian, a quarter of a mile above point where creek crosses international boundary in Saskatchewan, just across line from Buckley's ranch in United States, and 35 miles north of Chinook, Mont.

DRAINAGE AREA.—Not measured.

RECORDS AVAILABLE.—April 1 to September 30, 1917.

GAGE.—Stevens water-stage recorder referred to two vertical staff gages, one in well and one outside; read by John Buckley.

DISCHARGE MEASUREMENTS.—Made from cable 45 feet below gage or by wading.

CHANNEL AND CONTROL.—Bed composed of heavy boulders with sand and gravel; not likely to shift except during extreme stages.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 8.50 feet at 9.40 a. m. April 13 (discharge, 3,200 second-feet); minimum stage recorded, 1.96 feet August 13 (discharge, 0.6 second-foot).

ICE.—Records not maintained during winter. Stage-discharge relation seriously affected by ice April 1–10.

DIVERSIONS.—Several small ditches divert water for irrigation above station.

REGULATION.—None.

ACCURACY.—Stage-discharge relation practically permanent except for period April 1–10 when affected by ice. Rating curve well defined between 60 and 3,000 second-feet and fairly well defined below 60 second-feet, used April 16 to September 4; curve fairly well defined was used September 6–11. Daily gage heights determined from Stevens water-stage recorder April 16 to September 11, and from observer's readings twice daily September 12–30. Discharge determined by applying daily gage height to rating table. Discharge April 1–4 determined from the station at Nash's ranch 20 miles above; April 5–10 by interpolation between measurements of April 5 and 11; April 11–15 by computing discharge for hourly periods and averaging these discharges for each day; September 5 and 12–30 determined by shifting-control method. Records good.

COOPERATION.—Maintained in cooperation with Reclamation Service, Department of the Interior, Canada.

Discharge measurements of Battle Creek at international boundary during the year ending Sept. 30, 1917.

BATTLE CREEK[1] NEAR CHINOOK, MONT.

LOCATION.—In sec. 3, T. 33 N., R. 19 E., 500 feet above new highway bridge at point 4½ miles north of Chinook, in Blaine County, 7 miles above junction with Milk River.

DRAINAGE AREA.—Not measured.

RECORDS AVAILABLE.—April 22, 1905, to September 30, 1917.

GAGE.—Chain on left bank near house of R. B. Snedecor, 500 feet above the highway bridge; read by Mrs. R. B. Snedecor.

DICHARGE MEASUREMENTS.—Made by wading or from highway bridge.

CHANNEL AND CONTROL.—Sandy and shifting. Banks high and not subject to overflow. At low water principal control is sand bar below gage; no well-defined control at high water.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 11.8 feet at 7.10 p. m. April 10 (discharge, 6,380 second-feet); pool stage reported August 10 to September 9.

1905–1917: Maximum stage recorded, that of April 10, 1917; channel reported dry September 3 to October 22, 1905; July 8 to November 20, 1908; June 21 to end of year, 1910; July 22 to September 3, 1911; September 7–23, 1913; July 14 to October 4, 1914; and August 10 to September 9, 1917.

ICE.—Stage-discharge relation seriously affected by ice November 23 to April 1; observations discontinued January 1 to March 27.

[1] Decision of U. S. Geographic Board; formerly known as North Fork of Milk River.

DIVERSIONS.—Three canals, which divert about 20 second-feet, take out above the station in the United States, and several small pumping plants, which supply water for irrigating the bottom land along the valley, are also operated above the station. Below the station the Matheson and Cook canals divert water used to irrigate land in Milk River valley near the mouth of Battle Creek. For record of diversions by Cook and Matheson canals, see pages 86–87. About fifteen ditches divert water from this creek in Canada before it crosses the boundary line.

REGULATION.—None.

ACCURACY.—Stage-discharge relation affected by ice and shifting control. Rating curve well defined betweeen 40 and 700 second-feet used October 1 to November 22 and April 1–8; curve fairly well defined above 150 second-feet used April 9 to June 5; curve well defined below 100 second-feet used June 22 to August 5 and September 10–30. Gage heights from observer's readings to quarter-tenths or hundredths twice daily. Discharge determined by applying daily gage height to rating table; June 6–21 by shifting-control method. Records good.

Discharge measurements of Battle Creek near Chinook, Mont., during the year ending Sept. 30, 1917.

COOK CANAL NEAR CHINOOK, MONT.

Location.—In N. ½ sec. 30, T. 33 N., R. 20 E., half a mile below head gates and 3 miles east of Chinook, in Blaine County.

Records available.—April 10, 1905, to September 30, 1917.

Gage.—Vertical staff on left bank 1,000 feet above point where canal turns west and runs parallel to road; read by Adam Jamison.

Discharge measurements.—Made by wading near point where canal passes under Great Northern Railway.

Channel and control.—No well-defined control. Weeds grow in canal and frequently cause backwater.

Accuracy.—Owing to delay in making repairs to flume and head gates, very little water was used in 1917. Canal was in operation during June and July; records fair.

Canal diverts water from Battle Creek in SE. ¼ sec. 19, T. 33 N., R. 20 E., for irrigation of lands in the Milk River valley south of Milk River. Water can be wasted into Milk River at point where canal crosses river in a flume about 2 miles below gage. Flume sometimes acts as throttle when too much water is turned into canal.

Discharge measurements of Cook canal near Chinook, Mont., during the year ending Sept. 30, 1917.

MATHESON CANAL NEAR CHINOOK, MONT.

Location.—In NW. ¼ sec. 29, T. 33 N., R. 20 E., at farm bridge forming head gate of canal, a quarter of a mile north of main road and 3½ miles east of Chinook, in Blaine County.

Records available.—April 10, 1905, to September 30, 1917.

Gage.—Vertical staff on right bank 10 feet below head gate; read by Adam Jamison.

Discharge measurements.—Made by wading.

Channel and control.—Bed of canal is earth; no well-defined control. Aquatic plants in bottom of canal during summer may cause backwater.

Accuracy.—Stage-discharge relation permanent. Rating curve well defined below 7 second-feet and applicable June 27 to July 28. Gage heights from observer's readings to hundredths once daily. Discharge by applying gage height to rating table. Records fair.

Water is diverted from Battle Creek and used to irrigate lands on north side of Milk River valley. Water can be wasted into a small tributary of Milk River.

The following discharge measurement was made by A. H. Tuttle:

July 14, 1917: Gage height, 3.95 feet; discharge, 7.0 second-feet.

Daily discharge in second-feet, of Matheson canal near Chinook, Mont., for the year ending Sept. 30, 1917.

Monthly discharge of Matheson canal near Chinook, Mont., for the year ending Sept. 30, 1917.

Month.	Discharge in second-feet.			Run-off in acre-feet.
	Maximum.	Minimum.	Mean.	
June 26-30	2.7	0	1.54	15.3
July	7.6	0	4.10	252
The period				267

Note.—Canal was in operation June 27 to July 28. Canal was dry during remainder of year, except possibly during the high water in spring, when the river overflowed into the canal, but no records were obtained.

PARADISE CANAL NEAR CHINOOK, MONT.

LOCATION.—In SW. ¼ sec. 35, T. 33 N., R. 20 E., 300 feet below head gate, 30 feet below flume of Cook canal, on ranch of Rudolph Friede, 6 miles southeast of Chinook, in Blaine County, and 3 miles southwest of Zurich.

RECORDS AVAILABLE.—June, 1903, to August, 1909; and January 1, 1911, to September 30, 1917.

GAGE.—Vertical staff on left bank, 300 feet below head gate and 30 feet below flume carrying Cook canal over Paradise Valley canal; read by Rudolph Friede.

DISCHARGE MEASUREMENTS.—Made by wading.

CHANNEL AND CONTROL.—Bed of canal is earth; silt is deposited during irrigation season. Weeds grow in bottom of canal during summer. A large slough into which the canal flows a few hundred feet below gage may affect results, the height of the water in the slough possibly affecting the slope of the water surface at the gage.

ACCURACY.—Stage-discharge relation affected by shifting control. Measurements made June 23, August 1 and 9, and point of zero flow give a well-defined curve below 12 second-feet which is applicable June 5 to July 12; and July 26 to September 30. Gage read to hundredths twice daily; records June 5 to September 30. Discharge determined by applying daily gage height to rating table. Shifting-control method used July 13–25. Records good.

Paradise canal diverts water from Milk River to irrigate land on the south side of Milk River valley. No water is returned to river.

Discharge measurements of Paradise canal near Chinook, Mont., during the year ending Sept. 30, 1917.

The period				1,364

NOTE.—Water standing in pools June 5-15, 17-21, Sept. 22-25, and 28-30.

HARLEM CANAL NEAR ZURICH, MONT.

LOCATION.—In SW. ¼ sec. 33, T. 33 N., R. 21 E., 500 feet below head gates and 1½ miles southeast of Zurich, in Blaine County.

RECORDS AVAILABLE.—June, 1903, to September 30, 1917.

GAGE.—Vertical staff on right bank, 500 feet below head gates; read by Howsan Kirby.

DISCHARGE MEASUREMENTS.—Made by wading.

CHANNEL AND CONTROL.—Bed of canal is earth with no definite control. Check weirs several miles below gage may cause some backwater at high stages. Aquatic plants growing in canal during the irrigation season also cause backwater, and much silt is deposited.

ACCURACY.—Stage-discharge relation shifted during year. Rating curve well defined between 30 and 85 second-feet used April 19 to June 11 and July 10-27; curve well defined between 35 and 50 second-feet used July 28 to September 30. Gage read to hundredths twice daily. Discharge determined by applying mean daily gage height to rating table. Discharge June 12 to July 9 determined by shifting-control method because of silt in canal. Records fair.

Water is diverted from Milk River to irrigate lands on north side of river near Harlem. Water can be wasted into Milk River, but most of the water diverted is used.

Discharge measurements of Harlem canal near Zurich, Mont., during the year ending Sept. 30, 1917.

AGENCY DITCH NEAR HARLEM, MONT.

Location.—In NW. ¼ S.W. ¼ sec. 33, T. 32 N., R. 23 E., at spillway 1,000 feet below highway bridge, half a mile below head gate, and 4 miles south of Harlem, in Blaine County.

Records available.—July 14, 1905, to September 30, 1917.

Gage.—Vertical staff on right-hand downstream post of check weir at spillway; read by Estey M. Knapp.

Discharge measurements.—Made from bridge.

Channel and control.—Bed of canal is earth; backwater is caused by aquatic plants growing in the canal during irrigation season, and also by check gate 1 mile below station; that due to diversion at check gate varies with the quantity of water diverted.

Accuracy.—Stage-discharge relation affected by placing and removing checks below gage. Measurements made June 18, August 1, and August 9 give a well-defined curve beween 0 and 45 second-feet when checks below gage are in place. A parallel curve drawn through measurement made July 14 gives a rating curve for the time when checks below gage are removed. Gage read to tenths twice daily. Checks were removed June 26 and date of replacing is uncertain. Curve for period when checks were in place was used June 15–21 and July 31 to August 11. Curve for periods when checks were not in place was used June 26 to July 16. Shifting-control method used July 17–30. Records fair.

The canal takes water from Milk River for the irrigation of lands on Fort Belknap Indian Reservation. Water not required for irrigation can be wasted into White Bear Creek, 12 miles below head gate. This canal has been given a prior right by court decree to 125 second-feet of the water of Milk River and tributaries above the point of diversion.

Discharge measurements of Agency ditch near Harlem, Mont., during the year ending Sept. 30, 1917.

NOTE.—Irrigation season ended Aug. 11.

FRENCHMAN RIVER AT INTERNATIONAL BOUNDARY.

LOCATION.—In SW. ¼ sec. 4, T. 1, R. 10 W. third meridian at Ball's ranch, in Saskatchewan, just across the international boundary from east side of lot 3, sec. 6, T. 37 N., R. 34 E. in United States.

DRAINAGE AREA.—1,875 square miles (measured by Reclamation Service, Department of Interior, Canada).

RECORDS AVAILABLE. April 1 to September 30, 1917.

GAGE.—Stevens water-stage recorder referred to staff gage in well was used after April 5. Mrs. W. B. Chamberlain read gage during year.

DISCHARGE MEASUREMENTS.—Made from cable 20 feet above gage or by wading.

CHANNEL AND CONTROL.—Bar composed of boulders and gravel forms principal control at low and medium stage. At high stages this bar is drowned out and control is below.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 9.99 feet at 11.30 a. m. April 30 (discharge, 2,780 second-feet); minimum flow occurred during winter, lowest measurement being March 27 (discharge, 5.2 second-feet).

ICE.—Stage-discharge relation seriously affected by ice during winter.

Diversions.—Several ditches divert water for irrigation 60 miles above station in Saskatchewan.

Regulation.—None.

Accuracy.—Stage-discharge relation fairly permanent during the year when not affected by ice. Rating curve used April 12 to September 30 well defined between 20 and 2,820 second-feet. Gage heights April 6 to September 30 from automatic record. Discharge ascertained by applying gage height to rating table. Records fair, April 1–11; good, April 12 to end of year.

Cooperation.—Station maintained in cooperation with Reclamation Service, Department of Interior, Dominion of Canada.

Discharge measurements of Frenchman River at international boundary during the year ending Sept. 30, 1917.

BEAVER CREEK NEAR MALTA, MONT.

LOCATION.—In NW. ¼ sec. 30, T. 28 N., R. 33 E., on highway at Hales crossing, at site of proposed reservoir of United States Reclamation Service, 28 miles southeast of Malta, in Phillips County.

DRAINAGE AREA.—Not measured.

RECORDS AVAILABLE.—March 31 to September 30, 1917.

GAGE.—Chain gage on downstream handrail of highway bridge; read by Charles Hales.

DISCHARGE MEASUREMENTS.—Made from highway bridge or by wading at old ford crossing, 500 feet above bridge.

CHANNEL AND CONTROL.—Channel is straight for 150 feet above and 200 feet below gage. Banks are high and practically without vegetation. Left bank is overflowed at gage height 18.5 feet. The low-water control is gravel and cobblestone bar, 400 feet below gage; probably shifting. At stages above gage height 12.5 feet the river cuts across the first oxbow below and has a decided increase of slope, materially increasing the discharge. Stage of zero flow about 0.10 foot.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 19.5 feet April 6 (discharge, 4,990 second-feet); no flow July 1 to September 30.

ICE.—Creek freezes practically solid during winter and ice jams are frequent during the spring breakup.

DIVERSIONS.—No diversion from main stream; several on small tributaries above.

REGULATION.—None.

ACCURACY.—Stage-discharge relation not affected by ice or shifting control. Rating curve well defined between 10 and 3,000 second-feet. Gage read to hundredths once daily. Daily discharge obtained by applying daily gage heights to rating table. Records good.

ROCK CREEK NEAR HINSDALE, MONT.

LOCATION.—In sec. 10, T. 31 N., R. 36 E., at Ottenstror's ranch, 2 miles below head gates of Rock Creek canal and 6 miles northeast of Hinsdale, in Valley County.

DRAINAGE AREA.—Not measured.

RECORDS AVAILABLE.—April 19, 1912, to September 30, 1917. From July 5, 1905, to December 31, 1907, data were obtained at a station 2 miles upstream, just below the diversion dam of the Rock Creek canal. Flow at these two points is practically the same.

GAGE.—Combined overhanging chain and staff gage on left bank, back of John Ottenstror's house; chain gage reads to 16.0 feet; staff 16.0 to 24 feet. Original gage washed out during spring flood of 1917 and new one, installed 30 feet above old site, is now in use; read by Mrs. John Ottenstror and John Hoerster.

DISCHARGE MEASUREMENTS.—Made by wading a quarter of a mile below gage or from bridge 2 miles below.

CHANNEL AND CONTROL.—Water at gage is deep and sluggish at low stages. Control is a gravel bar a quarter of a mile below; shifts slightly at high water. Left bank high and is not overflowed at gage; right bank fairly high but is overflowed at flood stages.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 20.0 feet at 6 a. m. April 11 (discharge, 4,020 second-feet); no flow after September 13.

1906–1907 and 1912–1917: Maximum stage recorded, 18.40 feet June 9, 1906, determined by leveling from flood marks (discharge, determined from extension of rating curve, 6,220 second-feet); no flow April 14 to May 2, May 9–24, and after July 12, 1906; after September 28, 1907; April 23, 25, 27, 28, 30, May 1, 2, and 4, 1913; May 3, 5, 8, 10, and 13, 1915; and after September 13, 1917.

ICE.—Stage-discharge relation seriously affected by ice. Observations discontinued during winter.

DIVERSIONS.—There is no storage, but the normal summer flow is appropriated and used during the irrigation season.

REGULATION.—None.

ACCURACY.—Stage-discharge relation affected by ice and shifting control. Rating curve well defined between 0 and 300 second-feet used October 1 to November 25 and May 5 to June 5; curve fairly well defined between 0 and 3,400 second-feet used April 9–27 and June 28 to September 30. Gage read to tenths daily by Mrs. J. Ottenstror until July 4, and by John Hoerster after August 19; no records July 15 to August 18. Discharge determined by applying gage height to rating table; shifting-control method used April 28 to May 4, June 6–19, and June 20–27. Records fair.

Discharge measurements of Rock Creek near Hinsdale, Mont., during the year ending Sept. 30, 1917.

PORCUPINE CREEK AT NASHUA, MONT.

Location.—In sec. 31, T. 28 N., R. 42 E., 500 feet above ford, a quarter of a mile mile above highway bridge, three-eights of a mile north of Nashua, in Valley County.

Drainage area.—Not measured.

Records available.—July 11, 1908, to September 30, 1917.

Gage.—Vertical staff in three sections nailed to trees on the left bank; read by Rosie Brocksmith.

Discharge measurements.—Made by wading near gage or, at high stages, from a bridge a quarter of a mile below.

Channel and control.—Bed of stream is mud. Slight gravel bar forms the control at low stages. This is soon drowned out, as the creek rises, and the control is the whole channel below gage.

Extremes of discharge.—Maximum stage recorded during year, 16.6 feet at 8 a. m. April 10 (discharge, 1,080); no flow most of the time after June 30.

1909–1917: Maximum stage recorded, 18.0 feet, April 11, 1916, determined by leveling from flood marks (discharge, determined from extension of rating curve, 2,700 second-feet); no flow during periods in 1909, 1910, 1911, 1913, 1916, and 1917.

Ice.—Stage-discharge relation seriously affected by ice. Discharge very small. Observations discontinued during winter.

Diversions.—None during 1917. A United States Reclamation Service canal is practically completed which will divert the entire flow during irrigation season.

Regulation.—None developed. A United States Reclamation Service reservoir on the middle fork of stream will partially regulate flood flow.

Accuracy.—Stage-discharge relation not permanent; affected by shifting control and seriously affected by ice. Rating curve used October 1 to November 18, well defined below 60 second-feet, and fairly well defined to 1,000 second-feet. curve used April 1 to June 1 well defined between 7 and 1,000 second-feet; June 12 to July 12 fairly well defined. Shifting-control method used June 2 to 10, Gage read to tenths twice daily during fluctuating stage and once daily at other times. Daily discharge ascertained by applying daily gage height to rating table. Records fair.

Discharge measurements of Porcupine Creek at Nashua, Mont., during the year ending Sept. 30, 1917.

NOTE.—Creek standing in pools after June 29 except July 6-7, 9-10, when approximately 0.2 second-foot was flowing.

POPLAR RIVER BASIN.

POPLAR RIVER NEAR POPLAR, MONT.

LOCATION.—In S. ½ sec. 8, T. 28 N., R. 51 E., at United States Reclamation Service camp 5 miles north of Poplar, in Sheridan County.

DRAINAGE AREA.—Not measured.

RECORDS AVAILABLE.—October 5, 1913, to September 30, 1917, at present site; August 15, 1908, to June 30, 1911, in S. ½ sec. 5, T. 28 N., R. 51 E., at Obershaw's ranch, 6 miles north of Poplar; May 2, 1911, to October 4, 1913, at United States Reclamation camp in NE. ¼ sec. 4, T. 29 N., R. 51 E., 18 miles north of Poplar.

GAGE.—Chain gage on left bank at United States Reclamation Service camp; read by Art Pronovort and F. W. Cothren, employees of Reclamation Service.

DISCHARGE MEASUREMENTS.—Made by wading near gage or from highway bridge at Poplar, 8 miles below.

CHANNEL AND CONTROL.—Composed of gravel, clay, and boulders; shifts slightly, usually at extreme stages.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 10.95 feet at 8 a. m., April 14 (discharge, 5,280 second-feet); minimum stage recorded, 3.75 feet July 31 to August 4 (discharge, 1.5 second-feet).

1908–1917: Maximum stage recorded, 12.0 feet April 10, 1912; determined by leveling from flood marks (discharge, determined from extension of rating curve, 10,000 second-feet); minimum stage, 3.75 feet July 31 to August 4, 1917 (discharge, 1.5 second-feet).

[illegible] feet July [illegible]

ICE.—Stage-discharge relation seriously affected by ice November 29 to December 5; April 3–9. Discharge estimated November 29–30 at 47 and 43 second-feet, respectively. No records December 6 to April 2.

DIVERSIONS.—Poplar River canals, East and West, diverted water above gage for irrigation of approximately 10,000 acres. When the system of reservoirs is completed about 28,000 acres can be irrigated. Low flow during July, August, and September owing to the fact that all the water was diverted above station.

REGULATION.—None.

ACCURACY.—Stage-discharge relation not permanent, affected by shifting control and by ice. Daily gage heights are the mean of two readings daily during high water, and one reading daily at other times. Daily discharge October 1 to May 14 obtained from rating curve well defined below 1,800 second-feet; June 11 to September 30 from a rating curve well defined between 5 and 120 second-feet; May 15 to June 10 by shifting-control method. Low flow July 14 to September 18 represents return water and seepage only, as all the water is diverted above. Water was turned into the river on September 18.

BIG MUDDY CREEK BASIN.

BIG MUDDY CREEK NEAR CULBERTSON, MONT.

LOCATION.—In NE. ¼ sec. 20, T. 29 N., R. 54 E., at Kraft's (formerly Sholtz's) ranch, 11 miles above mouth of stream, 15 miles northwest of Culbertson, in Sheridan County, and 8 miles above site of original station at Boyd's ranch, which was discontinued.

DRAINAGE AREA.—Not measured.

RECORDS AVAILABLE.—July 19, 1909, to September 30, 1917, at present station; July 14, 1908, to July 19, 1909, at original station.

GAGE.—An inclined staff on left bank near the house on Kraft's ranch. Since August 19, 1916, read by Jacob Kraft. This gage has been read since July 19, 1909. Previous to that date a staff gage at Boyd's ranch, 8 miles downstream, was read.

DISCHARGE MEASUREMENTS.—Made by wading or from bridge about 9 miles below gage.

CHANNEL AND CONTROL.—A bar of gravel with a few small boulders forms the extreme low-water control; but this is soon drowned out, as the creek rises, and the control is the whole bed of the stream below. The creek has a very small slope, crooked channel, and mud banks which are fairly high and are seldom overflowed. Weeds grow thick in the channel above the control during summer, and cause backwater at gage.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 11.10 feet April 16, 17, 18 (discharge, 1,460 second-feet); minimum stage recorded during year, 1.70 feet August 22, 23, and September 13 (discharge, 0.5 second-foot).

1909–1917: Maximum stage recorded, 11.4 feet March 31, 1916 (discharge, 1,550 second-feet); minimum stage, 1.5 feet September 16–18, 1915 (discharge, 0).

ICE.—Little, if any, flow during winter.

DIVERSIONS.—Several small pumping plants divert water for irrigation above station; amount unknown.

REGULATION.—None.

ACCURACY.—Stage-discharge relation not permanent; seriously affected by ice and by occasional shifts in control. Rating curve used October 1 to November 11, fairly well defined below 30 second-feet; curve used March 30 to September 30, well defined. Gage read to half-tenths once daily. Daily discharge ascertained by applying daily gage height to rating table. Records fair, October and November; good, April to September.

Discharge measurements of Big Muddy Creek near Culbertson, Mont., during the year ending Sept. 30, 1917.

YELLOWSTONE RIVER BASIN.

YELLOWSTONE RIVER NEAR CANYON HOTEL, YELLOWSTONE NATIONAL PARK.

Location.—Approximately in sec. 16, T. 13 S., R. 10 E. Montana meridian, half a mile upstream from Upper Falls and Canyon soldier station, 1½ miles south of Canyon Hotel, and 13 miles below outlet of Lake Yellowstone.

Drainage area.—1,280 square miles (measured on topographic maps).

Records available.—June 23, 1913, to September 30, 1917.

Gage.—Friez water-stage recorder on left bank, 450 feet above Chittenden Bridge, and 900 feet below former vertical staff installed October 11, 1916, at about same datum. Vertical staff used September 13, 1913, to October 11, 1916. Original gage used June 22 to September 12, 1913, was of same type and at same site but set to datum 1.03 feet higher than later staff. Readings on original gage reduced to datum of later staff. Gage read by privates and noncommissioned officers attached to Canyon soldier station.

Discharge measurements.—Made by wading at low stages at a gravel and boulder section 100 feet below former staff gage. High-stage measurements made from cable one-fifth of a mile above new gage.

Channel and control.—One channel at all stages. Bed of stream composed of gravel and boulders; control formed by upper portion of the Upper Yellowstone Falls and is practically permanent.

Ice.—Stage-discharge relation affected by ice; gage reading discontinued during winter.

Extremes of discharge.—Maximum stage recorded during year, 4.08 feet at 4.30 p. m. July 11 (discharge, 7,220 second-feet); minimum stage recorded, 1.00 foot at 11 a. m. May 12 (discharge, 875 second-feet). A less gage height and discharge occurred during period of no record.

1913–1917: Maximum stage recorded, 4.08 feet at 4.30 p. m., July 11, 1917 (discharge, 7,220 second-feet); minimum stage recorded, 0.75 foot October 16, 1915 (discharge, 675 second-feet). A less gage height and discharge occurred during periods of no records.

Diversions.—None above station.

Regulation.—None.

Accuracy.—Stage-discharge relation practically permanent. Gage read once daily to half-tenths prior to May 26, except during winter. Rating curve is well defined. Daily discharge ascertained by applying daily gage height to rating table prior to May 26. After that date, daily discharge ascertained by applying mean daily height obtained by inspection of recorder graph to rating table. Records good.

Discharge measurements of Yellowstone River near Canyon Hotel, Yellowstone National Park, during the year ending Sept. 30, 1917.

September	2,270	1,420	1,790	107,000

YELLOWSTONE RIVER AT CORWIN SPRINGS, MONT.

LOCATION.—In NE. ¼ sec. 30, T. 8 S., R. 8 E., at highway bridge in canyon at Corwin Springs, in Park County, 8 miles below Gardiner, northern entrance to Yellowstone National Park.

DRAINAGE AREA.—2,630 square miles.

RECORDS AVAILABLE.—September 2, 1910, to September 30, 1917.

GAGE.—Chain gage fastened to floor of highway bridge on downstream side near right bank. Before October 25, 1911, staff gage set to same datum and fastened to pile beside concrete abutment on right bank. Gage read by Mrs. C. H. Wilks and Mrs. Lena Bassett.

DISCHARGE MEASUREMENTS.—Made from downstream side of highway bridge.

CHANNEL AND CONTROL.—Bed of stream composed of small rocks. Current swift at all stages; no definite control visible but has not shifted since station was established. Banks high and not subject to overflow.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 9.6 feet June 25 (discharge, 20,200 second-feet); minimum stage recorded, 0.7 foot February 9 (discharge, 870 second-feet).

1910–1917: Maximum stage recorded, 10.2 feet June 13, 1911 (discharge, 22,800 second-feet); minimum stage recorded, 0.6 foot January 1, 1916 (discharge, 830 second-feet).

ICE.—On account of missing gage readings and severe ice conditions for short period, the flow for the months of December and January was not computed; February 18 and 19 was estimated on account of anchor ice at 970 second-feet.

DIVERSIONS.—No water diverted from the Yellowstone above station.

REGULATION.—Yellowstone Lake furnishes a natural but uncontrolled regulation.

ACCURACY.—Stage-discharge relation permanent since station was established, except during ice-affected periods. Rating curve well defined between 1,000 and 18,300 second-feet. Gage read to half-tenths once daily. Gage not read on October 17, December 10–14, December 27 to January 5, January 18–24. Daily discharge ascertained by applying gage height to rating table, except October 17, when discharge was interpolated, and February 18–19, when discharge was estimated on account of ice. Records for open channel are good. There may have been slight ice effect during November and February, and records for these months may be slightly high.

No discharge measurements were made at this station during the year.

Daily discharge, in second-feet, of Yellowstone River at Corwin Springs, Mont., for the year ending Sept. 30, 1917.

YELLOWSTONE RIVER AT INTAKE, MONT.

LOCATION.—In NW. ¼ sec. 36, T. 18 N., R. 56 E., at Lower Yellowstone diversion dam at Intake, in Dawson County, 18 miles below Glendive.

DRAINAGE AREA.—Not measured.

RECORDS AVAILABLE.—January 1, 1911, to September 30, 1917. At Glendive, 18 miles above, by War Department and Department of Agriculture 1893 to 1903, and by Geological Survey, August 1, 1903, to December 31, 1910.

GAGE.—Chain gage on north abutment of dam showing depth of water on crest; read by Howard Roby and Matt Griebler, employees of United States Reclamation Service.

DISCHARGE MEASUREMENTS.—Made from bridge at Glendive.

Channel and control.—Dam forming the principal control is a rock filled timber crib structure on pile foundation, completed January 29, 1910; 700 feet long; crosses the stream at right angles to current, and raises low-water level about 4 feet; specially designed to resist the destructive effects of ice by approach on a slope of 3 to 1; downstream face is ogee-shaped and protected by a heavy rock apron.

Extremes of discharge.—Maximum stage recorded during year, 15 and 16 feet at 8 a. m. April 3 (stage-discharge relation affected by ice jam 2½ miles below; discharge not computed); minimum stage recorded, 1.2 feet November 15 (discharge, 4,040 second-feet). A lower stage may have occurred during frozen period.

1903–1917: Maximum stage, open channel recorded, 10.1 feet July 4, 1912 (discharge, 112,000 second-feet); minimum stage recorded, 0.9 foot December 26–28 (discharge, 2,950 second-feet).

Ice—Stage-discharge relation seriously affected by ice January 1 to April 3; flow not computed.

Diversions.—The Lower Yellowstone canal, which divers water to irrigate 66,000 acres of land, heads at north abutment of dam. There are also many diversions on the tributaries above station.

Regulation.—Yellowstone Lake and Shoshone reservoir form the only important regulation above, and control only a small part of the flood flow.

Accuracy.—Stage-discharge relation permanent, except as affected by ice. Rating curve fairly well defined by discharge measurements made at Glendive and curve of relation between gage heights at Glendive and at Lower Yellowstone dam. Gage read to tenths twice daily, except for period January 6 to March 23 when they are estimated from hole cut in ice near gage. Daily discharge ascertained by applying mean daily gage height to rating table. Records fair.

No discharge measurements made during year.

Daily discharge, in second-feet, of Yellowstone River at Intake, Mont., for the year ending Sept. 30, 1917.

BIG TIMBER CREEK NEAR BIG TIMBER, MONT.

Location.—In SE. ¼ sec. 5, T. 2 N., R, 14 E., at Webb's ranch, 4 miles below junction of forks of Big Timber Creek and 9 miles northwest of Big Timber, in Sweetgrass County.

Drainage area.—Not measured.

Records available.—April 13, 1912, to September 30, 1917.

Gage.—Chain gage on left bank below lower barns, and about one-eighth of a mile below house at Webb's ranch; read by L. E. Webb to May 21. This was destroyed by high water and on August 8, 1917, a temporary overhanging chain gage was set on left bank opposite sheep sheds and 500 feet above site of old gage. Read by John Kremper.

Discharge measurements.—Made by wading.

Channel and control.—Bed and banks are of gravel and boulders and are subject to change at each high stage.

Extremes of discharge.—Maximum stage recorded during year, 4.10 feet May 12 (discharge, 212 second-feet); minimum stage, 3.25 feet October 5-7 and November 12 (discharge, 18 second-feet).

1912-1917: Maximum stage recorded, 4.8 feet June 5, 1914 (discharge, 937 second-feet); minimum stage, 2.65 feet March 20, 1915 (discharge, 7 second-feet).

Ice.—Stage-discharge relation seriously affected by ice; observations discontinued during winter.

Diversions.—Numerous irrigating ditches divert water both above and below the gage.

Regulation.—None.

Accuracy.—Stage-discharge relation entirely changed by high water of June, requiring a new gage location; stage-discharge relation unchanged at new site during period of record. Rating curves fairly well defined. Gage read to half-tenths daily to May 21 and twice daily August 8 to September 30. Daily discharge ascertained by applying mean daily gage height to rating tables except for October 1, interpolated. Records fair.

SWEETGRASS CREEK ABOVE MELVILLE, MONT.

Location.—About in middle of sec. 27, T. 5 N., R. 13 E., on T. S. Lavold's ranch, 9 miles northwest of Melville, in Sweet Grass County.

Drainage area.—About 63 square miles (measured on topographic map).

Records available.—August 21, 1913, to September 30, 1917; May 5, 1907, to December 31, 1912, for station at C. M. Reins's ranch in SW. ¼ sec. 24, T. 5 N., R. 12 E., 17 miles northwest of Melville. No diversions or tributaries between two stations.

Gage.—Vertical staff on left bank three-fourths of a mile above T. S. Lavold's house; read by T. S. Lavold.

Discharge measurements.—Made by wading 100 feet above gage or from bridge near observer's house.

Channel and control.—Stream bed of gravel and boulders; slightly shifting. Banks high; not subject to overflow.

Extremes of discharge.—Maximum stage during year, 3.2 feet June 10 (discharge, 1,260 second-feet) ;minimum stage, 0.5 foot November 13–14 (discharge, 13 second-feet).

1907–1912: Maximum stage recorded at old section, 5.15 feet June 1, 1908 (discharge, 1,490 second-feet); minimum stage, 1.42 feet April 18–19, 1911, and April 23–30, 1912 (discharge, 8.6 second-feet).

1913–1917: Maximum stage recorded at present site, 2.7 feet June 4, 1914 (discharge, 1,280 second-feet); minimum stage, 0.45 foot April 29, 1915 (discharge, 11 second-feet).

Ice.—Stage-discharge relation seriously affected by ice. Observations discontinued during winter.

DIVERSIONS.—Two small ditches divert water above gage; quantity diverted is negligible.

REGULATION.—None.

ACCURACY.—Stage-discharge relation fairly permanent. Rating curve well defined below 700 second-feet. Gage read to half-tenths once daily. Daily discharge ascertained by applying daily gage height to rating table. Records good.

SWEETGRASS CREEK BELOW MELVILLE, MONT.

Location.—Near middle of south line of sec. 27, T. 4 N., R. 15 E., at Crum's ranch, a quarter of a mile above head of intake canal of Big Timber Carey project and 6 miles southeast of Melville, Sweet Grass County.

Drainage area.—137 square miles (measured on topographic maps).

Records available.—April 1, 1909, to November 10, 1916; and August 8 to September 30, 1917. May 4, 1907, to April 1, 1909, at Adam's ranch 2½ miles downstream.

Gage.—Overhanging chain gage on left bank 100 feet west of Crum's house; read by Swen Johnson October 1 to November 10; and by Chas. E. Crum August 8 to September 30.

Discharge measurements.—Made by wading or from highway bridge half a mile above gage.

Channel and control.—Stream bed of clean gravel; bar producing riffle 300 feet around a bend below gage, likely to shift. Right bank low; subject to overflow during high stages; left bank is a cut bank at the gage and not overflowed at that point, but is lower and may be subject to overflow about 200 feet below gage.

Extremes of discharge.—Maximum stage recorded during year 1.97 feet at 7.30 a. m. August 9 (discharge, 95 second-feet); minimum stage 1.2 feet October 1, 2, 13, and 14 (discharge 38 second-feet).

1909–1917: Maximum stage recorded, 4.2 feet during June high water, as estimated on June 27, 1916, from high-water marks (discharge, from extension of rating table, 1,700 second-feet); minimum stage recorded, 1 foot August 23–25, September 2–4 and 6, 1913 (discharge, 10 second-feet).

Ice.—Stage-discharge relation seriously affected by ice; no record for ice period.

Diversions.—There are adjudicated rights from Sweetgrass Creek amounting to over 500 second-feet, and numerous ditches divert water both above and below station. The intake canal of the Big Timber Carey project, which will carry 600 second-feet, diverts into two connecting storage reservoirs, one of 6,000, and the other 12,000 acre-feet capacity.

Regulation.—None.

Accuracy.—Stage-discharge relation changed during period of no records from November 11 to August 7; both rating curves used are fairly well defined. Gage read to half-tenths once daily October 1 to November 10, 1916; and to hundredths twice daily after August 7, 1917. Daily discharge ascertained by applying mean daily gage height to rating table. Records fair.

PRYOR CREEK AT COBURN, MONT.

Location.—In SE. ¼ sec. 35, T. 1 S., R. 27 E., on Crow Indian Reservation at Coburn, in Yellowstone County, 12 miles southwest of Billings and 13 miles above mouth of creek.

Drainage area.—Not measured.

Records available.—September 13, 1911, to September 30, 1917.

Gage.—Overhanging chain gage on left bank, opposite observer's house; read by Harry Foster.

Discharge measurements.—Made by wading.

Channel and control.—Bed of stream gravel and clay. Principal control is gravel bar which forms a riffle at low stages about 300 feet below gage; at a medium stage the riffle disappears and no well defined control exists. Both banks high and not subject to overflow except at extreme stages. Current at gage is sluggish at low stages but of medium velocity at high stages.

Extremes of discharge.—Maximum stage recorded during year, 10.44 feet at 7 p. m. June 5 (discharge, 750 second-feet); minimum stage recorded, 4.1 feet August 25 and 30, September 4 (discharge, 20 second-feet).

1911–1917: Maximum stage recorded, that of June 5, 1917; minimum stage, 3.6 feet September 1, 1913 (discharge, 6 second-feet).

ICE.—Stage-discharge relation seriously affected by ice; observations discontinued during winter.

DIVERSIONS.—Water sufficient to irrigate approximately 1,000 acres near Pryor is diverted about 30 miles above Coburn.

REGULATION.—None.

ACCURACY.—Stage-discharge relation not permanent; affected by shift in control and by ice. Rating curve used October 1 to November 20 and April 8 to June 8 well defined between 14 and 282 second-feet; curve used June 19 to August 31 fairly well defined; shifting-control method used June 9-18 and September 1-30. Gage read to half-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records good.

Discharge measurements of Pryor Creek at Coburn, Mont., during the year ending Sept. 30, 1917.

WIND RIVER AT RIVERTON, WYO.

LOCATION.—In sec. 2, T. 1 S., R. 4 E., at highway bridge three-fourths of a mile east of Riverton, in Fremont County. Popo Agie River enters three-fourths of a mile below.

DRAINAGE AREA.—2,320 square miles (measured on base map of Wyoming; scale, 1:500,000).

RECORDS AVAILABLE.—May 15, 1911, to October 31, 1912; April 1, 1915, to September 30, 1917. From May 14, 1906, to November 1, 1908, a station was maintained at Walker's ferry about 1 mile above present station. No streams enter between the sites; records directly comparable.

GAGE.—Friez water-stage recorder installed April 4, 1917; referred to chain gage on downstream side of first pier bent from left. This chain gage used previous to installation of recorder.

DISCHARGE MEASUREMENTS.—Made from bridge.

CHANNEL AND CONTROL.—Channel composed of sand and gravel; high water during 1917 formed large sand bar just below gage completely changing the control. Right bank will overflow at extreme high water.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year 10.9 feet at 7.30 a. m. July 1 (discharge, 9,530 second-feet); minimum discharge occurs during winter.

ICE.—Stage-discharge relation seriously affected by ice.

DIVERSIONS.—Water is diverted from Wind River and its tributaries for the irrigation of approximately 27,000 acres. Under the Wyoming law of 1 second-foot for 70 acres, this would require 386 second-feet.

REGULATION.—None.

ACCURACY.—Stage-discharge relation shifted seriously during high water of 1917; affected by ice during winter. Rating curve used October 1 to July 31 well defined between 300 and 8,000 second-feet; and curve used August 1 to September 30 fairly well defined between 400 and 3,000 second-feet. Gage read to quarter-tenths October 1 to November 11. Operation of the water-stage recorder was satisfactory April 4 to September 30. Daily discharge ascertained by applying to the rating table mean daily gage height determined from two daily gage readings and by inspecting the gage-height graph. Records excellent, except for periods June 20 to August 15 when they are fair, and August 16 to September 30 when they are good.

Discharge measurements of Wind River at Riverton, Wyo., during the year ending Sept. 30, 1917.

BIG HORN RIVER AT THERMOPOLIS, WYO.

LOCATION.—In sec. 36, T. 43 N., R. 95 W., at highway bridge between Thermopolis and Hot Springs, Hot Springs County. Nearest tributary, Buffalo Creek, enters 3 miles upstream.

DRAINAGE AREA.—8,080 square miles (measured on base map of Wyoming; scale, 1:500,000).

RECORDS AVAILABLE.—May 28, 1900, to December 31, 1905; June 30, 1910, to October 7, 1912; April 1, 1915, to September 30, 1917. State engineer maintained station at this point during 1913 and 1914.

GAGE.—Chain gage on downstream handrail on bridge, installed May 4, 1916, at datum 1 foot lower than staff gage used previously; read by Mrs. H. E. Holdrege and Miss Florence Erlos.

DISCHARGE MEASUREMENTS.—Made from two-span bridge.

CHANNEL AND CONTROL.—Channel composed of coarse gravel and small boulders. Control a short distance below gage; practically permanent. High-water control is vertical walls of canyon entrance half a mile downstream. Banks high and not subject to overflow.

EXTREMES OF DISTANCE.—Maximum stage recorded during year, 13.4 feet at 7 p. m. June 24, and 6 p. m. June 27 (discharge, 19,400 second-feet); minimum discharge occurs during winter.

ICE.—Stage-discharge relation affected by ice. Records discontinued during winter.

DIVERSIONS.—Prior to December 31, 1916, there were adjudications of 41 second-feet from Big Horn River above station and 202 second-feet below. In addition there is an adjudicated diversion of 366 second-feet for power above station.

REGULATION.—None.

ACCURACY.—Stage-discharge practically permanent; affected by ice during winter. Rating curve well defined between 800 and 17,000 second-feet. Gage read to quarter-tenths twice daily. Daily discharge ascertained by applying the mean daily gage height to rating table. Records excellent.

Discharge measurements of Big Horn River at Thermopolis, Wyo., during the year ending Sept. 30, 1917.

[Made by P. V. Hodges].

BIG HORN RIVER NEAR HARDIN, MONT.

LOCATION.—In SW. ¼ sec. 13, T. 1 S., R. 33 E., at bridge of Chicago, Burlington & Quincy Railroad on Crow Indian Reservation, half a mile above junction of Big Horn and Little Horn rivers, 2 miles from Hardin, in Big Horn County.

DRAINAGE AREA.—20,700 square miles.

RECORDS AVAILABLE.—June 16, 1904, to September 30, 1917.

GAGE.—Chain gage attached to west span, upstream side of railroad bridge; read by H. R. Kean. A temporary staff gage 20 feet farther downstream was used October 11 to November 22, 1913, and the readings reduced to datum of chain gage.

DISCHARGE MEASUREMENTS.—Made from railroad bridge.

CHANNEL AND CONTROL.—Stream bed gravel; free from vegetation; slightly shifting. Banks high and not subject to overflow.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 9.90 feet June 26 (discharge, 36,700 second-feet); minimum discharge recorded, 625 second-feet by current-meter measurement January 25.

1904–1917: Maximum stage recorded, 9.8 feet June 17, 1908 (discharge, 40,800 second-feet); minimum discharge recorded that of January 15, 1917.

ICE.—Stage-discharge relation seriously affected by ice December 9, 1916, to March 24, 1917.

DIVERSIONS.—Water is diverted a few miles above station, by a private irrigation company, to irrigate land on west side of river. Water is also diverted from Shoshone River at Corbett dam, Wyo., by United States Reclamation Service, and many private ditches divert water from tributaries above station.

REGULATION.—Shoshone reservoir above Cody controls flow of Shoshone River, an important tributary of the Big Horn.

ACCURACY.—Stage-discharge relation affected by ice and by shifting control. Rating curve used October 1 to December 8 fairly well defined between 3,020 and 14,500 second-feet; curve used March 25 to July 1 well defined between 800 and 34,000 second-feet; July 6 to September 30 well defined between 1,600 and 8,000 second-feet; shifting control method used July 2–5. Gage read to half-tenths once daily. Daily discharge ascertained by applying daily gage height to rating table. Discharge December 9 to March 24 determined from observer's notes, weather records, and six discharge measurements. Records good for open flow; only fair for winter.

Discharge measurements of Big Horn River near Hardin, Mont., during the year ending Sept. 30, 1917.

POPO AGIE RIVER BELOW ARAPAHOE, WYO.[1]

Location.—In sec. 23, T. 1 S., R. 3 E., at highway bridge half a mile below Arapahoe, Fremont County. Nearest tributary, Little Wind River, enters 200 yards above. Popo Agie River joins Wind River 6 miles below to form Big Horn River.

Drainage area.—1,530 square miles (measured on base map of Wyoming, scale 1:500,000).

Records available.—May 11, 1906, to November 27, 1909; May 14, 1911, to October 31, 1912; April 1, 1915, to September 30, 1917.

Gage.—Vertical staff on downstream side of first pier from left bank; read by R. H. Knox. From June 19 to July 19, 1911, a temporary gage was used with datum 2.95 feet higher; during 1915, a temporary gage was used with datum 0.55 foot higher. All readings have been reduced to the original datum.

Discharge measurements.—Made from highway bridge or by wading.

Channel and control.—Bed composed of sand and gravel. Control slightly shifting from year to year. Right bank will be overflowed at high water.

Extremes of discharge.—Maximum stage recorded during year, 9.3 feet for several days during latter part of June from high-water mark (discharge, 9,710 second-feet); minimum discharge probably occurs during winter.

Diversions.—Between this station and that on Little Wind above Arapahoe, there were adjudicated diversions of 583 second-feet from the Popo Agie and its tributaries, prior to December 31, 1916.

Regulation.—None.

Accuracy.—Stage-discharge relation slightly shifting; affected by ice during winter. Rating curve used October 1 to November 9 well defined between 100 and 400 second-feet; curve used April 1 to September 30 well defined between 200 and 6,000 second-feet but not well defined above 6,000 second-feet. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records excellent up to 6,000 second-feet; above this they are fair.

Discharge measurements of Popo Agie River below Arapahoe, Wyo., during the year ending Sept. 30, 1917.

LITTLE POPO AGIE RIVER AT HUDSON, WYO.

LOCATION.—About sec. 12, T. 2 S., R. 2 E., at highway bridge three-eighths of a mile southwest of Hudson, Fremont County. No tributary between station and mouth of river, half a mile below.

DRAINAGE AREA.—346 square miles (measured on base map of Wyoming; scale, 1:500,000).

RECORDS AVAILABLE.—August 26, 1907, to December 31, 1909; June 19, 1911, to October 31, 1912; April 1, 1915, to September 30, 1917.

GAGE.—Vertical staff on downstream side of center pier of bridge, installed August 25, 1915, at datum 1 foot higher than that of original gage, a vertical staff attached to right abutment and used from August 26, 1907, to June 12, 1908; June 13, 1908, chain gage was installed 100 yards downstream from bridge and at a new datum; chain gage was abandoned July 24, 1912, and readings were resumed on the original gage, which was also used from April 1 to August 25, 1915. Gage read by Mrs. A. C. Ladd.

Discharge measurements.—Made from bridge or by wading.

Channel and control.—Bed composed of sand and gravel washed in from new channel cut above station during winter of 1915. Control is at gage; permanent during 1917.

Extremes of discharge.—Maximum stage recorded during year, 6.6 for about one week, June 19–26, as determined by leveling to high-water marks (discharge, 1,490 second-feet); minimum discharge occurs during winter.

Ice.—Stage-discharge relation seriously affected by ice; observations discontinued during winter.

Diversions.—Prior to December 31, 1916, adjudicated diversions from Little Popo above the station amounted to 50 second-feet.

Regulation.—None.

Accuracy.—Stage-discharge relation practically permanent; affected by ice during winter. Rating curve well defined between 40 and 800 second-feet but poorly defined above 800 second-feet. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records excellent up to 800 second-feet; above this they are fair.

Discharge measurements of Little Popo Agie River at Hudson, Wyo., during the year ending Sept. 30, 1917.

LITTLE WIND RIVER ABOVE ARAPAHOE, WYO.

Location.—In sec. 23, T. 1 S., R. 3 E., at railroad bridge opposite Indian subagency, a quarter of a mile above Arapahoe, Fremont County. Little Wind River enters Popo Agie River a quarter of a mile below station.

Drainage area.—716 square miles (measured on base map of Wyoming; scale, 1:500,000).

Records available.—May 14, 1911, to October 31, 1912; April 1, 1915, to September 30, 1917. From May 11, 1906, to December 17, 1909, a station was maintained a short distance above present one. The flow at the two points is comparable.

Gage.—Chain gage on upstream side of railroad bridge; read by R. H. Knox.

Discharge measurements.—Made from single-span bridge.

Channel and control.—Channel composed of sand and gravel. Control a short distance downstream; shifted slightly during 1917. Banks high and not subject to overflow.

Extremes of discharge.—Maximum stage recorded during year, 6.25 feet, mornings of June 23, 24, and 26 (discharge, 3,280 second-feet). Records discontinued during winter, when minimum discharge probably occurs.

Ice.—Stage-discharge relation seriously affected by ice; records discontinued during winter.

Diversions.—Water is diverted from Little Wind River and tributaries for the irrigation of approximately 52,000 acres. Under the Wyoming law of 1 second-foot for 70 acres, this would require 742 second-feet.

Regulation.—None.

Accuracy.—Stage-discharge relation not permanent; affected by ice during winter. Rating curve well defined between 40 and 3,000 second-feet. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table, except for periods April 8 to May 31 and July 16 to September 30, when discharge was computed by the shifting-control method. Records good.

Discharge measurements of Little Wind River above Arapahoe, Wyo., during the year ending Sept. 30, 1917.

OWL CREEK NEAR THERMOPOLIS, WYO.

LOCATION.—About sec. 16, T. 43 N., R. 95 W., at Whetstine's ranch 6 miles northwest of Thermopolis, Hot Springs County. No tributary between station and mouth.

DRAINAGE AREA.—463 square miles (measured on base map of Wyoming; scale, 1:500,000).

RECORDS AVAILABLE.—July 30, 1910, to October 31, 1912; April 1, 1915, to November 30, 1917, when station was discontinued. Station maintained by State engineer during 1913 and 1914.

GAGE.—Slope gage installed October 13, 1915, at footbridge 50 feet downstream from chain gage used by State engineer, and referred to same datum; read by W. E. Whetstine. Owing to slope of creek, slope gage reads approximately 0.1 foot lower. Chain gage on upstream side of highway bridge a quarter of a mile above used from 1910 to 1912. No definite relation between the gage readings.

DISCHARGE MEASUREMENTS.—Made from footbridge or by wading.

CHANNEL AND CONTROL.—Bed composed of compact gravel. Control 100 feet downstream at small rapids which remained fairly permanent during 1917. Right bank not subject to overflow; left bank is overflowed at stage about 6.6 feet.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 6.8 feet at 7 p. m. June 17 (discharge, 980 second-feet); minimum discharge occurs during winter.

ICE.—Stage-discharge relation seriously affected by ice; observations discontinued during winter.

DIVERSIONS.—Prior to December 31, 1916, there were adjudicated diversions of 116 second-feet from Owl Creek above station and 66 second-feet below.

REGULATION.—None.

ACCURACY.—Stage-discharge relation practically permanent; affected by ice during winter. Rating curve well defined up to 600 second-feet. Gage read to quarter-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records probably good; reliability of gage-height record questioned.

Discharge measurements of Owl Creek near Thermopolis, Wyo., during the year ending Sept. 30, 1917.

NO WOOD CREEK AT BONANZA, WYO.

LOCATION.—In sec. 13, T. 49 N., R. 91 W., at Bonanza, Big Horn County. Nearest tributary, Paintrock Creek, enters some distance above.

DRAINAGE AREA.—1,790 square miles (measured on base map of Wyoming, scale 1:500,000).

RECORDS AVAILABLE.—July 29, 1910, to October 31, 1912; April 1, 1915, to September 30, 1917.

GAGE.—Chain on left bank 1,000 feet below the store at Bonanza; read by Mrs. W. E. Taylor. Datum may be slightly different from that used 1910 to 1912, as bench mark had been destroyed and there was no means of checking the old gage.

DISCHARGE MEASUREMENTS.—Made from two-span highway bridge a quarter of a mile below gage or by wading.

CHANNEL AND CONTROL.—Bed of channel composed of gravel. Control 100 feet downstream at small rapids, which shift between narrow limits.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 7.2 feet at 8 a. m. June 18 (discharge, 3,480 second-feet); minimum discharge probably occurred during winter.

ICE.—Stage-discharge relation seriously affected by ice; observations discontinued during winter.

DIVERSIONS.—Prior to December 31, 1916, there were adjudicated diversions of 80 second-feet from No Wood Creek above station and 42 second-feet below; all for irrigation. In addition, there is a decree for a power diversion of 115 second-feet below.

ACCURACY.—Stage-discharge relation shifts slightly at long intervals; rating curve well defined throughout; gage read to quarter-tenths once daily. Daily discharge ascertained by applying daily gage heights to rating table. Records good.

Discharge measurements of No Wood Creek at Bonanza, Wyo., during the year ending Sept. 30, 1917.

[Made by P. V. Hodges.]

TENSLEEP CREEK NEAR TENSLEEP, WYO.

LOCATION.—In sec. 12, T. 47 N., R. 88 W., 800 feet east of county bridge at Burke's ranch, 5 miles above Tensleep, Washakie County. Nearest tributary, Canyon Creek, enters a quarter of a mile upstream.

DRAINAGE AREA.—228 square miles (measured on base map of Wyoming; scale, 1:500,000.

RECORDS AVAILABLE.—September 21, 1910, to December 31, 1912; April 19, 1915, to September 30, 1917.

GAGE.—Inclined staff on left bank, 800 feet above county bridge, opposite vertical rock cliff; read by Lynn Burke.

DISCHARGE MEASUREMENTS.—Made from cable 100 feet below gage or by wading.

CHANNEL AND CONTROL.—Bed composed of coarse gravel and small boulders. Control just below gage at rapids; fairly permanent in 1917. Right bank is vertical rock cliff; left bank subject to overflow at extremely high water.

Extremes of discharge.—Maximum stage recorded during year, 5.8 feet at 7 a. m. June 18 (discharge, 1,860 second-feet); minimum stage occurs during winter.

Ice.—Stage-discharge relation not seriously affected by ice. Open-channel rating curve assumed applicable.

Diversions.—There is a diversion of approximately 8 second-feet for power above the station. Prior to December 31, 1916, there were adjudicated diversions of 35 second-feet for irrigation, all below station.

Regulation.—None.

Accuracy.—Stage-discharge relation slightly shifting; only slightly affected by ice. Rating curve well defined between 40 and 800 second-feet, not well defined above 800 second-feet. Gage read to hundredths once daily, except during high water when it is read twice daily. Daily discharge ascertained by applying daily gage reading or the mean of two daily gage readings to the rating table, except for period October 1 to January 20, when the discharge is computed by the shifting-control method. Records excellent below 800 second-feet and fair above.

Discharge measurements of Tensleep Creek near Tensleep, Wyo., during the year ending Sept. 30, 1917.

PAINTROCK CREEK NEAR BONANZA, WYO.

Location.—About sec. 19, T. 49 N., R. 90 W., at Paumer's ranch, 1½ miles above Bonanza, Big Horn County. No tributary between station and mouth half a mile below.

Drainage area.—398 square miles (measured on base map of Wyoming; scale, 1:500,000).

Records available.—July 28, 1910, to October 31, 1912; April 19, 1915, to September 30, 1917.

Gage.—Chain on right bank 300 feet below ranch; read by Mrs. Wm. Paumer; used since April 11, 1917. From April 19, 1915, to November 18, 1916, staff gage at same location and datum. From July 28, 1910, to October 31, 1912, there was a chain gage near house. No definite relation between gages at two locations, as high water changed channel between.

Discharge measurements.—Made from cable 65 feet below gage or by wading nearby.

Channel and conrtol.—Bed composed of gravel; control at rapids composed of small boulders 150 feet below gage; somewhat shifting. The right bank is low and is overflowed at stage of 2 feet.

Extremes of discharge.—Maximum stage recorded during year, 4.2 feet at 7 a. m. June 17 (discharge, 2,180 second-feet); minimum discharge probably occurs during winter.

Ice.—Stage-discharge relation seriously affected by ice; observations discontinued during winter.

Diversions.—Prior to December 31, 1916, there were adjudicated diversions of 66 second-feet from Paintrock Creek, practically all being above station.

Regulation.—None.

Accuracy.—Stage-discharge relation slightly shifting; affected by ice during winter. Rating curve used October 1 to November 10 well defined between 20 and 200 second-feet; curve used April 11 to September 30 well defined between 20 and 1,800 second-feet. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records excellent.

Discharge measurements of Paintrock Creek near Bonanza, Wyo., during the year ending Sept. 30, 1917.

WOOD RIVER NEAR MEETEETSE, WYO.

Location.—Near line between secs. 26 and 27, T. 48 N., R. 101 W., 1,200 feet above mouth of Wood River and 7 miles southwest of Meeteetse, Park County.

Drainage area.—218 square miles (measured on base map of Wyoming; scale, 1:500,000).

Records available.—September 15, 1910, to October 31, 1912; May 10, 1915, to September 30, 1917, when station was discontinued.

Gage.—Chain gage on left bank 400 feet above bridge, used since April 25, 1916; read by Mrs. Adah River. Original gage, used during 1910–1912, was vertical staff at bridge. Vertical staff at bridge, but referred to different datum from original gage, used from May 10, 1915, to April 24, 1916.

Discharge measurements.—Made from cable short distance below gage.

Channel and control.—Channel composed of boulders; control a short distance below gage at small rapids; shifted considerably during 1917. Right bank will be overflowed at extremely high water.

EXTREMES OF STAGE.—Maximum stage recorded during year, 4.4 feet at 5 p. m. May 15; minimum discharge probably occurs during winter when records are discontinued.

ICE.—Stage-discharge relation seriously affected by ice; observations discontinued during winter.

DIVERSIONS.—Prior to December 31, 1916, there were adjudicated diversions of 66 second-feet from Wood River.

REGULATION.—None.

ACCURACY.—Stage-discharge relation shifts seriously; affected by ice during winter. Rating curve used October 1 to November 11 well defined between 50 and 100 second-feet. Gage read to quarter-tenths once daily. Daily discharge ascertained by applying daily gage height to rating table. Records good for October and November. Data inadequate for determination of discharge April 10 to September 30.

Discharge measurements of Wood River near Meeteetse, Wyo., during the year ending Sept. 30, 1917.

October	84	66	75.4	4,640
November 1-11	71	52	62.3	1,360

SHELL CREEK AT SHELL, WYO.

LOCATION.—Near the western edge of sec. 26, T. 53 N., R. 91 W., 450 feet above head gate of Shell canal, three-quarters of a mile northeast of Shell, Big Horn County. Nearest tributary, Trapper Creek, enters a short distance above.

DRAINAGE AREA.—256 square miles (measured on base map of Wyoming; scale, 1:500,000).

RECORDS AVAILABLE.—April 1, 1915, to September 30, 1917. From July 1, 1911, to October 31, 1914, station maintained by Wyoming Irrigation Co. and published in reports of State engineer.

GAGE.—Vertical staff on right bank 450 feet above canal head gate; read by J. G. Tatlock.

DISCHARGE MEASUREMENTS.—Made from suspension footbridge at gage or by wading at same section.

CHANNEL AND CONTROL.—Bed composed of gravel. Control just below gage at gravel bar which may shift during high water. Banks not subject to overflow.

EXTREMES OF DISCHARGE. Maximum stage recorded during year, 7.75 feet at 12.30 p. m., June 17 (discharge, 1,500 second-feet); minimum discharge probably occurred during winter.

ICE.—No information as records are discontinued during winter.

DIVERSIONS.—Prior to December 31, 1916, there were adjudicated diversions of 8 second-feet from Shell Creek above the station, and 104 second-feet below.

REGULATION.—Flow controlled to a certain extent by storage of water in Adelaide reservoir, located on Shell Creek, 25 miles above Shell; capacity of reservoir 1,410 acre-feet. Water stored in reservoir beginning of high-water period and released in latter part of summer.

ACCURACY.—Stage-discharge relation not permanent. Rating curve well defined between 50 and 700 second-feet, but not well defined above 700 second-feet. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table, except for period June 29 to September 30, when discharge was computed by indirect method for shifting control. Records excellent up to 700 second-feet; above this they are good.

Discharge measurements of Shell Creek at Shell, Wyo., during the year ending Sept. 30, 1917.

SHOSHONE RIVER NEAR ISHAWOOA, WYO.

LOCATION.—On line between secs. 26 and 27, T. 51 N., R. 104 W., at Coe's private bridge, 1½ miles northeast of Ishawooa, Park County. Nearest tributary, Belknap Creek, enters at Ishawooa.

DRAINAGE AREA.—532 square miles (measured on base map of Wyoming; scale, 1:500,000).

RECORDS AVAILABLE.—May 7, 1915, to September 30, 1917.

GAGE.—Vertical staff on first right downstream piling of bridge; read by Miss Ina Spaulding and Loyd Spaulding.

DISCHARGE MEASUREMENTS.—Made from five-span pile bent bridge or by wading.

CHANNEL AND CONTROL.—Channel composed of boulders, control not well defined; shifts during high water. Right bank not subject to overflow; left bank will be overflowed at high stages.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 6.0 feet at 8.15 p. m. July 5 (discharge, 4,420 second-feet); minimum discharge probably occurred during winter.

ICE.—No information, as records are discontinued.

DIVERSIONS.—Prior to December 31, 1916, there were approved diversions of 26 second-feet from Shoshone River above the station and 40 second-feet above Shoshone reservoir.

REGULATION.—None.

ACCURACY.—Stage-discharge relation not permanent. Rating curve fairly well defined between 200 and 4,400 second-feet. Gage read to hundredths once daily. Daily discharge ascertained by applying daily gage height to rating table, except for period June 24 to September 30, when discharge was computed by indirect method for shifting control. Records good, except during high stages when they are only fair, owing to wave action at gage, and diurnal fluctuation.

Discharge measurements of Shoshone River near Ishawooa, Wyo., during the year ending Sept. 30, 1917.

SOAP CREEK NEAR ST. XAVIER, MONT.

LOCATION.—In sec. 20, T. 5 S., R. 32 E., at Henry Reed's ranch, 9 miles south of St. Xavier and 1 mile above mouth of stream, in Big Horn County.

DRAINAGE AREA.—Not measured.

RECORDS AVAILABLE.—September 11, 1911, to September 30, 1917. April 25, 1914, to June 12, 1915, at Frank Annerer's ranch, half a mile above present site; September 11, 1911, to November 30, 1913, in W. ½ NW. ¼ sec. 2, T. 6 S., R. 32 E., a quarter of a mile above headworks of Soap Creek ditch.

GAGE.—Overhanging chain gage on right bank opposite Henry Reed's house; read by Henry Reed. Original gage, in use September 11, 1911, to November 30, 1913, was overhanging chain gage about a quarter of a mile above headworks of Soap Creek ditch; gage used April 25, 1914, to June 12, 1915, a chain gage on footbridge near Frank Annerer's house, a quarter of a mile above present site.

DISCHARGE MEASUREMENTS.—Made by wading or from highway bridge 1 mile upstream from gage.

CHANNEL AND CONTROL.—Bed of stream at principal control is composed of gravel and silt; shifts slightly. Stage-discharge relation affected at times by growth of aquatic plants in channel.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 11.69 feet March 25, determined by level from stake set by observer at water level during heavy ice jam (discharge not computed); minimum stage recorded, 2.80 feet August 13 (discharge, 11 second-feet).

1911–1917: Maximum stage recorded, 12.8 feet May 11, 1914, determined by leveling from flood marks (discharge, determined from extension of rating curve, 438 second-feet); minimum stage recorded, 2.1 feet September 10, 1914 (discharge, 1 second-foot).

ICE.—Stage-discharge relation seriously affected by ice November 11 to March 24. Flow not computed; gage heights were obtained November 12 to December 31.

DIVERSIONS.—Soap Creek ditch diverts above station during summer for irrigation.

REGULATION.—None.

ACCURACY.—Stage-discharge relation not permanent; seriously affected by ice during winter and by shifting control May 30 to September 30. Rating curve used October 1 to November 11 poorly defined; curve used April 1 to May 29 fairly well defined; indirect method for shifting control used May 30 to September 30. Gage read to hundredths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records October 1 to November 11 are poor; April 1 to September 30 fair.

Discharge measurements of Soap Creek near St. Xavier, Mont., during the year ending Sept. 30, 1917.

ROTTENGRASS CREEK NEAR ST. XAVIER, MONT.

LOCATION.—In NW. ¼ sec. 6, T. 5 S., R. 23 E., a quarter of a mile above crossing of Big Horn canal, on Crow Indian Reservation, 4 miles south of St. Xavier, in Big Horn County.

DRAINAGE AREA.—Not measured.

RECORDS AVAILABLE.—September 9, 1911, to September 30, 1917.

GAGE.—Overhanging chain on left bank a quarter of a mile above crossing of Big Horn canal; read by Loren S. Stanley.

DISCHARGE MEASUREMENTS.—Made from footbridge 500 feet above gage or by wading.

CHANNEL AND CONTROL.—Bed of stream gravel and silt; shifts. Banks above and below gage high and steep; not subject to overflow below gage height 11 feet (discharge, about 400 second-feet).

EXTREMES OF DISCHARGE.—Maximum stage during year, 11.3 feet at 5.30 p. m. March 30 (discharge, from extension of rating curve, 500 second-feet); minimum stage recorded, 2.90 feet 6 p. m. August 16 (discharge, 2.5 second-feet).

1911–1917: Maximum stage recorded, 11.3 feet March 30, 1917 (discharge, 500 second-feet); minimum stage recorded, 2.3 feet September 27, 1911 (discharge 0.3 second-foot).

ICE.—Stage-discharge relation seriously affected by ice; observations discontinued November 10 to March 30.

DIVERSIONS.—None.

REGULATION.—None.

ACCURACY.—Stage-discharge relation changed by high water in March. Rating curve used October 1 to November 9 well defined below 100 second-feet; curve used March 30 to September 30 well defined below 60 second-feet. Gage read to half-tenths twice daily; read occasionally to quarter-tenths. Daily discharge ascertained by applying mean daily gage height to rating table. Records good.

LITTLE HORN RIVER NEAR WYOLA, MONT.

Location.—In W. ½ SW. ¼ sec. 28, T. 2 S., R. 35 E., a quarter of a mile below proposed headworks of Little Big Horn canal No. 3, 16 miles above Lodgegrass Creek, and 4 miles southwest of Wyola, in Big Horn County.

Drainage area.—260 square miles.

Records available.—September 7, 1911, to September 30, 1917.

Gage.—Overhanging chain gage on right bank; read by Ida M. Shipman and Granville Collins.

Discharge measurements.—Made from cable 75 feet below gage or by wading near cable.

Channel and control.—Composed of boulders and gravel; shifts occasionally at high stage. Left bank high and not subject to overflow; right bank high but subject to overflow 100 feet below gage.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 7.1 feet at 7 a. m. June 22 (discharge, 1,580 second-feet); minimum stage, 4.20 feet March 15–20 and 22–24 (discharge, 82 second-feet).

1912–1917: Maximum stage recorded, 7.1 feet June 22, 1917 (discharge, 1,580 second-feet); minimum stage, 4.2 feet April 10 and 12, 1915 (discharge, 32 second-feet).

ICE.—Stage-discharge relation seriously affected by ice; observations discontinued December 10 to March 11.

DIVERSIONS.—Small amount diverted for irrigation.

REGULATION.—None.

ACCURACY.—Stage-discharge relations not permanent; affected by shifting control and by ice. Rating curve used October 1 to April 15 well defined below 500 second-feet; shifting-control method used April 16 to September 30. Gage read to half-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records fair.

Discharge measurements of Little Horn River near Wyola, Mont., during the year ending Sept. 30, 1917.

LITTLE HORN RIVER NEAR CROW AGENCY, MONT.

LOCATION.—In W. ½ sec. 18, T. 3 S., R. 35 E., at Chicago, Burlington & Quincy Railroad bridge 2 miles south of Crow Agency, in Big Horn County, 14 miles above junction with Big Horn River.

DRAINAGE AREA.—1,190 square miles.

RECORDS AVAILABLE.—September 7, 1911, to September 30, 1917; March 24, 1905, to June 30, 1906, for station at Crow Agency, 2 miles below present station; Crow Agency ditch diverts water between the stations.

GAGE.—Stevens water-stage recorder on right bank 40 feet below railway bridge set to same datum as chain gage; chain gage on downstream side of railway bridge 1912 to 1916. Records for 1911 were obtained from staff on bridge pier near left bank; gages at same datum. Records 1905–6 obtained from chain gage on upstream side of railroad bridge at Crow Agency.

DISCHARGE MEASUREMENTS.—Made from upstream side of highway bridge 200 feet below gage or by wading.

CHANNEL AND CONTROL.—Bed of stream composed of gravel; slightly shifting. Banks high; not subject to overflow below gage height, about 14 feet.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 10.8 feet at 8 a. m. April 6 (discharge, 3,930 second-feet); minimum stage, 4.40 feet October 1–7, November 1, August 29 to September 9, September 14, 22–30 (discharge, 129 second-feet).

1905 and 1912–1917: Maximum stage recorded, 10.8 feet April 6, 1917 (discharge, 3,930 second-feet); minimum stage, 1.8 September 25–29, 1905 (discharge, 60 second-feet).

ICE.—Stage-discharge relation seriously affected by ice; observations discontinued during winter.

DIVERSIONS.—Several small diversions for irrigation from main stream and tributaries above station.

REGULATION.—None.

ACCURACY.—Stage-discharge relation permanent except as affected by ice. Rating curve well defined between 150 and 4,000 second-feet. Gage read to half-tenths once daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records good.

Discharge measurements of Little Horn River near Crow Agency, Mont., during the year ending Sept. 30, 1917.

[Made by W. A. Lamb.]

LODGEGRASS CREEK AT LODGEGRASS, MONT.

LOCATION.—In S. ½ sec. 13, T. 6 S., R. 35 E., 600 feet above Chicago, Burlington & Quincy Railroad bridge and a quarter of a mile south of Lodgegrass, on Crow Indian Reservation, in Big Horn County.

DRAINAGE AREA.—Not measured (142 square miles at old site, 6 miles upstream).

RECORDS AVAILABLE.—March 24, 1916, to September 30, 1917, at present site; September 9, 1911, to December 28, 1915, at old site 6 miles above in SW. ¼ sec. 29, T. 6 S., R. 35 E., a quarter of a mile above Lodgegrass ditch.

GAGE.—Overhanging wire gage on left bank; at old site, an overhanging chain gage at different datum.

DISCHARGE MEASUREMENTS.—Made from the railway bridge or by wading.

CHANNEL AND CONTROL.—Control is an outcrop of sandstone overlain by boulders and gravel; boulders and gravel likely to shift.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 5.05 feet March 31, when stage-discharge relation was affected by ice (discharge not computed); minimum stage, 1.85 feet October 1, 2, and 15 (discharge, 14 second-feet).

1911–1917: Maximum stage, 7.0 feet June 13, 1915 (discharge, 695 second-feet), minimum stage, 1.80 feet September 9 and 13, 1916 (discharge, 11 second-feet).

ICE.—Stage-discharge relation seriously affected by ice November 17 to March 31; flow not determined. No records December 23 to March 29.

DIVERSIONS.—Lodgegrass ditch diverts water for irrigation 6 miles above present site. Old station was a quarter of a mile above headworks of this ditch; hence flow during irrigation season is not comparable to that at present site.

REGULATION.—None.

ACCURACY.—Daily gage heights taken from observer's readings to nearest quarter-tenth once daily. Two readings were taken during rapid change in stage. Daily discharge obtained by applying daily gage heights to rating table, October 1 to November 17, April 16 to July 28, and August 10 to September 20. Discharge obtained April 1–15 and July 28 to August 9 by shifting-control method; records fair. Curve used October 1 to November 17 and April 16 to July 28 fairly well defined between 15 and 400 second-feet; records good.

Discharge measurements of Lodgegrass Creek at Lodgegrass, Mont., during the year ending Sept. 30, 1917.

TONGUE RIVER AT CARNEYVILLE, WYO.

LOCATION.—In sec. 20, T. 57 N., R. 84 W., at highway bridge at Carneyville, Sheridan County. Nearest important tributary, Goose Creek, enters 3 miles below.

DRAINAGE AREA.—495 square miles (measured on base map of Wyoming; scale, 1: 500,000).

RECORDS AVAILABLE.—May 25, 1911, to October 31, 1912; April 4, 1915, to June 30, 1917, when station was discontinued.

GAGE.—Chain gage on downstream side of bridge; read by Walter Bone.

DISCHARGE MEASUREMENTS.—Made from two-span bridge or by wading.

CHANNEL AND CONTROL.—Bed composed of gravel and small boulders; shifts; no well defined control. Banks not subject to overflow.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 7.3 feet at 11.30 a. m., June 18 (discharge, 2,690 second-feet); minimum stage probably occurred during winter.

ICE.—Stage-discharge relation seriously affected by ice; observations discontinued during winter.

DIVERSIONS.—Prior to December 31, 1916, there were adjudicated diversions of 188 second-feet from Tongue River above station and 33 second-feet below.

REGULATION.—None.

ACCURACY.—Stage-discharge relation not permanent; affected by ice during winter. Rating curve used October 1 to November 12 is fairly well defined between 100 and 1,400 second-feet and curve used June 15–30 is well defined between 100 and 2,800 second-feet; shifting-control method used April 8 to June 14. Gage read to quarter-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records good.

Discharge measurements of Tongue River at Carneyville, Wyo., during the year ending Sept. 30, 1917.

POWDER RIVER NEAR ARVADA, WYO.

LOCATION.—Near line between Tps. 56 and 57 N., R. 76 W., at State bridge 17 miles north of Arvada, Sheridan County. Nearest tributary, Clear Creek, enters 200 yards below.

DRAINAGE AREA.—6,580 square miles (measured on base map of Wyoming; scale, 1:500,000).

RECORDS AVAILABLE.—September 1, 1915, to September 30, 1917.

GAGE.—Chain gage on upstream guard-rail of bridge, since May 4, 1916; read by John Watt. Prior to that date, gage was inclined staff 1 mile upstream at K ranch.

DISCHARGE MEASUREMENTS.—Made from two-span highway bridge or by wading.

CHANNEL AND CONTROL.—Bed composed of silt and gravel. Control just above mouth of Clear Creek. During high water there may be backwater from Clear Creek as there is only 2 feet fall between station and creek.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 8 feet at 1.30 p. m. May 22 (discharge, 8,780 second-feet); minimum stage recorded, 475 feet on August 27 (discharge, 6 second-feet).

ICE.—Stage-discharge relation seriously affected by ice; observation discontinued during winter.

DIVERSIONS.—Prior to December 31, 1916, there were adjudicated diversions of 9 second-feet from Powder River above station and none below.

REGULATION.—None.

ACCURACY.—Stage-discharge relation fairly permanent, except for a short time during high water when it was affected by backwater from Clear Creek. Affected by ice during winter. Rating curve well defined below 2,000 second-feet but poorly defined above. Gage read to hundredths once daily. Daily discharge ascertained by applying daily gage height to rating table. Owing to flashy character of stream, one gage height per day will not give true mean stage for the day. Records fair.

Discharge measurements of Powder River near Arvada, Wyo., during the year ending Sept. 30, 1917.

CLEAR CREEK NEAR BUFFALO, WYO.

LOCATION.—In sec. 6, T. 50 N., R. 82 W., just above power house of Buffalo Manufacturing Co., 4 miles west of Buffalo, in Johnson County.

DRAINAGE AREA.—120 square miles (measured on topographic map).

Records available.—June 16 to September 30, 1917. From May 2, 1896, to February 28, 1900, station maintained at measuring flume 1 mile upstream. Flow at two points comparable. From October 24, 1902, to December 31, 1904, and May 8, 1911, to June 11, 1912, a station was maintained at highway bridge in Buffalo. Flow not comparable, as several ditches divert water between.

Gage.—Chain gage at left bank 300 feet above power house.

Discharge measurements.—Made from cable located 50 feet upstream from gage. Low-water measurements made by wading opposite power house.

Channel and control.—Channel composed of large boulders; control at large boulders 10 feet downstream; permanent during 1917. Banks low, but not subject to overflow because of small range of stage.

Ice.—Stage-discharge relation seriously affected by ice; records discontinued.

Extremes of discharge.—Maximum stage recorded 4.2 feet at 6.30 a. m. June 18 (discharge, 1,120 second-feet); minimum discharge occurred during winter.

Diversions.—Pipe line of Buffalo Manufacturing Co. diverts water from Clear Creek 1½ miles upstream. A separate record of flow through pipe line is kept and flow added to that at gaging station to give total flow of creek. Four lakes and French Creek canal had adjudicated decrees for diversion of 25 second-feet from North Fork into French Creek prior to December 31, 1916. During 1917, 10,360 acre-feet were diverted between June 10 and September 30. North Fork and French Creek canal diverted 1,230 acre-feet between June 10 and July 21. Below there are adjudicated decrees for diversion of 428 second-feet.

Regulation.—Alternate melting and freezing of snow in mountains during spring causes diurnal fluctuation in flow. No artificial regulation.

Accuracy.—Stage-discharge relation practically permanent; affected by ice during winter. Rating curve well defined between 10 and 800 second-feet. Gage read to half-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to rating table. Records good.

Discharge measurements of Clear Creek near Buffalo, Wyo., during the year ending Sept. 30, 1917.

CLEAR CREEK NEAR ARVADA, WYO.

LOCATION.—In sec. 36, T. 57 N., R. 77 W., at Sorenson's ranch, 1½ miles above mouth of creek and 16 miles north of Arvada, Sheridan County. No tributary between station and mouth of creek.

DRAINAGE AREA.—1,110 square miles (measured on base map of Wyoming; scale 1:500,000).

RECORDS AVAILABLE.—August 8, 1915, to September 30, 1917.

GAGE.—Chain gage on right bank a quarter mile below diversion dam at Sorenson's ranch; read by Miss Carrier Sorenson.

DISCHARGE MEASUREMENTS.—Made from cable 50 feet below gage or by wading.

CHANNEL AND CONTROL.—Bed composed of sand and gravel. Multiple control consisting of two rock dikes across the river 150 feet apart; upper dike 100 feet below gage acts as low-water control. At high water, lower dike is control. At low stages silt collects in the crevices of the rock dike changing the stage-discharge relation. Banks not subject to overflow. Stage of zero flow, 3.8 feet.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 8.2 feet at 7 p.m. June 18 (discharge, 2,630 second-feet); minimum discharge probably occurred during winter.

ICE.—Stage-discharge relation seriously affected by ice; observation discontinued during winter.

DIVERSIONS.—Prior to December 31, 1916, there were adjudicated diversions of 428 second-feet from Clear Creek.

REGULATION.—None.

ACCURACY.—Stage-discharge relation not permanent; affected by ice during winter. Rating curve well defined between 20 and 2,800 second-feet. Gage read to hundredths once daily except during flood stages when it was read twice daily. Daily discharge ascertained by applying to rating table the daily gage height, or the mean of two daily gage heights. Records good.

PINEY CREEK AT KEARNEY, WYO.

LOCATION.—In sec. 26, T. 53 N., R. 83 W., at highway bridge 300 yards south of Kearney, Johnson County.

DRAINAGE AREA.—117 square miles (measured on base map of Wyoming; scale, 1:500,000).

RECORDS AVAILABLE.—September 6, 1902, to June 30, 1906; May 13, 1911, to October 31, 1912; April 24, 1915, to July 31, 1917, when station was discontinued.

GAGE.—Chain gage on downstream side of bridge; read by Mrs. Lena Noyce. Gage used 1902–1916 was at same site but referred to different datum.

DISCHARGE MEASUREMENTS.—Made from single-span bridge or by wading.

CHANNEL AND CONTROL.—Bed composed of gravel and small boulders; control 100 feet downstream at well-defined rapids, which shifted slightly during 1917. At high water there is flow through a small channel at the left bank which diverts water from Piney Creek some distance above the station. Flow through this channel begins at stage of approximately 5 feet.

EXTREMES OF DISCHARGE.—Maximum stage recorded during year, 4.7 feet at 6 p. m June 17 (discharge, 1,220 second-feet); minimum discharge probably occurred during winter.

ICE.—Stage-discharge relation affected by ice; observations discontinued during winter.

DIVERSIONS.—Prior to December 31, 1916, there were adjudicated diversions of 278 second-feet from Piney Creek above station and 74 second-feet below.

REGULATION.—None.

ACCURACY.—Stage-discharge relation slightly shifting; affected by ice during winter. Rating curve well defined between 10 and 1,000 second-feet. Gage read to half-tenths twice daily. Daily discharge ascertained by applying mean daily heights to rating table, except for period June 8 to July 31, when discharge was computed by indirect method for shifting control. Records excellent.

Discharge measurements of Piney Creek at Kearney, Wyo., during the year ending Sept. 30, 1917.

July	298	32	132	8,12[illegible]

PINEY CREEK AT UCROSS, WYO.

LOCATION.—In NW. ¼ sec. 18, T. 53 N., R. 80 W., at highway bridge a quarter of a mile from Ucross, in Sheridan County. No tributary between station and mouth, half a mile below.

DRAINAGE AREA.—253 square miles (measured on base map of Wyoming; scale 1 : 500,000).

RECORDS AVAILABLE.—May 12 to September 30, 1917.

GAGE.—Chain gage attached to highway bridge; read by Miss Alma Larsen.

DISCHARGE MEASUREMENTS.—Made from highway bridge or by wading 200 feet downstream.

CHANNEL AND CONTROL.—Bed composed of silt and gravel which will shift. Control 50 feet downstream at riffle composed of compact gravel; shifted slightly during 1917. Banks not subject to overflow.

ICE.—Stage-discharge relation affected by ice.

EXTREME OF DISCHARGE.—Maximum stage recorded during period, 4.2 feet at 11 a. m. June 20 (discharge, 1,070 second-feet); minimum stage recorded, 1.3 feet at 8.20 a. m. July 20 (discharge, 4 second-feet).

DIVERSIONS.—Prior to December 31, 1916, adjudicated diversions of 351 second-feet from Piney Creek, all above station.

REGULATION.—Head waters are chain of small mountain lakes, the largest of which, Cloud Peak, is used as reservoir for irrigation. Alternate melting and freezing of mountain snow in spring of year causes some diurnal fluctuation.

ACCURACY.—Stage-discharge relation slightly shifting; affected by ice during winter. Rating curve well defined between 6 and 1,200 second-feet. Gage read to quarter-tenths twice daily. Daily discharge ascertained by applying mean daily gage height to the rating table; shifting-control method used August 21 to September 30. Records good, June 8 to August 20; fair, August 21 to September 30.

Discharge measurements of Piney Creek at Ucross, Wyo., during the year ending Sept. 30, 1917.
